then I have *proved* that the existence of capital is an eternal law of nature of human production and that the Kirghiz who cuts down rushes with a knife he has stolen from a Russian so as to weave them together to make a canoe is just as true a capitalist as Herr von Rothschild. I could prove with equal facility that the Greeks and Romans celebrated communion because they drank wine and ate bread, and that the Turks sprinkle themselves daily with holy water like Catholics because they wash themselves daily. This is the sort of impertinent and superficial rubbish that one finds doled out with self-important complacency not only by the likes of F. Bastiat* or the little economic pamphlets of the Society for the Advancement of Useful Knowledge, or the nursery stories of a Mother Martineau,† but even in the writings of reputable authorities. Far from demonstrating, as they hope, that capital is an eternal natural necessity, all they succeed in doing is to *refute* that necessary existence in the case of a specific historical phase of the social process of production. For if it is claimed that capital is nothing but the material and instruments of labour or that the material elements of the labour process are capital by nature, one may rightly riposte that in that event we do indeed require capital but no capitalists, or alternatively that capital is nothing but a *name* invented to deceive the masses.[8]

[8] 'We are told that Labour cannot move one step without Capital – that Capital is as a shovel to a man who digs – that Capital is just as necessary to production as Labour itself is. The working man knows all this, for its truth is daily brought home to him; but this mutual dependency between Capital and Labour has nothing to do with the relative position of the capitalist and the working man; nor does it show that the former could be maintained by the latter. Capital is but so much unconsumed produce; and that which is at this moment in being, exists now independent of, and is in no way identified with, any particular individual or class. Labour is the parent of it, on the one side, and mother earth upon the other; and were every capitalist and every rich man in the United Kingdom to be annihilated in one moment, not a single particle of wealth or capital would disappear with them; nor would the nation itself be less wealthy, even to the amount of one farthing. It is the capital, and not the capitalist, that is essential to the operations of the producer; and there is as much difference between the two, as there is between the actual cargo and the bill of lading' (J. F. Bray, *Labour's Wrongs and Labour's Remedy, etc.*, Leeds, 1839, p. 59).

'Capital is a sort of *cabalistic word* like church or state, or any other of

† Harriet Martineau, *Illustrations of Political Economy*, 9 vols., London, 1832–4.

The failure to comprehend the labour process as an independent thing and at the same time as an aspect of capitalist production becomes even more strikingly obvious when Mr F. Wayland, for example, tells us that *raw materials* are *capital* and that it is by treating them that we arrive at the product. Thus leather is the *product* of the currier and the *capital* of the shoemaker. Both 'raw material' and 'product' are terms referring to things in the *labour process* and in itself neither has anything to do with *capital* although both raw material and product represent *capital* the moment the labour process is appropriated by the capitalist.[9]

M. Proudhon has exploited all this with his customary 'profundity'. 'How does the *concept of a product* suddenly become transformed into the *concept of capital*? Through the *idea of value*. That is to say, in order to become capital the product must have undergone an authentic process of valuation, it must have been bought or sold, its price debated and established by a sort of legal convention. When a hide comes from a butcher it is the *product of the butcher*. Suppose the hide be now purchased by a currier. The latter immediately enters it or its value in his exploitation fund. Then, through the labour of the currier, this *capital* becomes a *product* once again.'[10] M. Proudhon distinguishes himself here by the apparatus of false metaphysics by means of which he first enters the most elementary notions as capital in his 'exploitation fund' and then sells them to the public as a high-sounding pro-

---

those general terms which are invented by those who fleece the rest of mankind to conceal the hand that shears them' (*Labour Defended against the Claims of Capital etc.*, London, 1825, p. 17). The author of this pamphlet is Th. Hodgskin, one of the most important modern English economists. Some years after its publication, the work cited, whose importance is still acknowledged (see, for example, John Lalor, *Money and Morals etc.*, London, 1852), was the occasion of an anonymous counter-pamphlet by Lord Brougham, whose response was noteworthy for the same superficiality that marks all the economic productions of that windbag.

[9] 'The material which . . . we obtain for the purpose of combining it with *our own* (!) industry, and forming it into a product, is called *capital*; and, after the labour has been exerted, and the value created, it is called a *product*. Thus the same article may be *product* to one, and *capital* to another. Leather is the product of the currier, and the capital of the shoemaker' (F. Wayland, op. cit., p. 25).

[10] There now follows the above-quoted shit from Proudhon, *Gratuité du Crédit. Discussion entre M. Fr. Bastiat et M. Proudhon*, Paris, 1850, pp. 179, 180 and 182.

duct. The question of how *products* can be turned into *capital* is essentially nonsensical, but the answer proves worthy of the question. In actual fact M. Proudhon merely informs us of two fairly well-known facts: first, that products sometimes serve as raw materials to be processed, and second, that *products* are also *commodities*, i.e. they possess a *value* which has to withstand the ordeal of an interchange between buyer and seller before it can be realized. The same 'philosopher' remarks: '*La différence, pour la société, entre capital et produit n'existe pas. Cette différence est toute subjective aux individus*.' He calls the abstract social form 'subjective' and his subjective abstraction he calls 'society'.

As long as the economist looks at the process of capitalist production only in the context of the *labour process*, he declares that capital is a mere *article*, raw material, an instrument, etc. But it then occurs to him that the process of production is also the valorization process and that in the latter the articles come into consideration only as a *value*. 'The same capital exists now in the form of a sum of money, now in the form of raw material, an instrument, a finished product. These *articles* are not actually *capital*; capital resides in the *value* they possess.'[11] In so far as this value 'maintains itself, endures, multiplies itself, detaches itself
469d from the commodity that has created it and remains, like a metaphysical and insubstantial quality, always in the possession of the same producer (i.e. the capitalist)'[12] the same thing which was just declared to be an *article*, is now deemed 'a *commercial idea*'.

The product of capitalist production is neither a mere *product* (a use-value), nor just a *commodity*, i.e. a product with an exchange-value, but a *product specific to itself*, namely *surplus-value*. Its product is *commodities* that possess more exchange-value, i.e. represent more labour than was invested for their production in the shape of money or commodities. In capitalist production the

---

[11] Cf. J. B. Say, op. cit. [*Traité d'économie politique*], Vol. II, p. 429, note. When Carey says, '*Capital* . . . all articles possessing exchangeable value' (H. C. Carey, *Principles of Political Economy*, Part I, Philadelphia, 1837, p. 294) this lapses into the explanation of capital referred to in Chapter I*: 'Capital – is commodities', an explanation that can only refer to the manifestation of capital in the process of circulation.

[12] Sismondi, *Nouv. Princ. etc*., Vol. I, p. 89. Cf. also '*Le capital est une idée commerciale*' ['Capital is a commercial idea'] (Sismondi, *Études, etc*., Vol. II, p. 389).

*See above, p. 255, n. 13.

labour process is only the *means*; the end is supplied by the *valorization process* or the *production of surplus-value.* As soon as this occurs to the economist he declares capital to be wealth which is used in production to make a 'profit'.[13]

We have seen that the transformation of money into capital breaks down into two wholly distinct, autonomous spheres, two entirely separate processes. The first belongs to the realm of the *circulation of commodities* and is acted out in the *market-place.* It is the *sale and purchase of labour-power.* The second is the *consumption* of *the labour-power that has been acquired,* i.e. the process of production itself. In the first process the capitalist and the worker confront one another merely as the owners respectively of money and commodities, and their transactions, like those of all buyers and sellers, are the exchange of equivalents. In the second process the worker appears *pro tempore* as the living component of capital itself, and the category of exchange is entirely excluded here since the capitalist has acquired by purchase all the factors of the production process, both material and personal, before the negotiations begin. However, although the two processes subsist independently side by side, each conditions the other. The first introduces the second and the second completes the first.

The first process, the *sale and purchase of labour-power,* displays to us the capitalist and the worker only as the buyer and seller of commodities. What distinguishes the worker from the vendors of other commodities is only the *specific nature,* the *specific use-value,* of the commodity he sells. But the particular use-value of a commodity does not affect the economic form of the transaction; it does not alter the fact that the purchaser represents money, and the vendor a commodity. In order to *demonstrate,* therefore, that the relationship between capitalist and worker is nothing but a relationship between commodity owners who exchange money and commodities with a free contract and to their mutual advantage, it suffices to isolate the first process and to cleave to its formal character. This simple device is no sorcery, but it contains the entire wisdom of the vulgar economists.

---

[13] '*Capital.* That portion of the stock of a country which is kept or employed with a view to profit in the production and distribution of wealth' (T. R. Malthus, *Definitions in Political Economy,* new edition, etc. by John Cazenove, London, 1853, p. 10). 'Capital is the part of wealth employed for production and generally for the purpose of obtaining profit' (Th. Chalmers, *On Political Economy, etc.,* London, 1832, 2nd edn, p. 75).

We have seen that the capitalist must transform his money not only into labour-power, but into the material factors of the labour process, i.e. the means of production. However, if we think of the whole of capital as standing on one side, i.e. the totality of the purchasers of labour-power, and if we think of the totality of the vendors of labour-power, the totality of workers on the other, then we find that the worker is compelled to sell not a commodity but his own labour-power as a commodity. This is because he finds on the other side, opposed to him and confronting him as alien property, all the means of production, all the material conditions of work together with all the means of subsistence, money and means of production. In other words, all *material wealth confronts* the worker as the property of the *commodity possessors.* What is proposed here is that he works as a *non-proprietor* and that the *conditions of his labour confront* him as *alien property.* The fact that Capitalist No. 1 owns money and that he buys the means of production from Capitalist No. 2, who owns them, while the worker buys the means of subsistence from Capitalist No. 3 with the money he has obtained from Capitalist No. 2, does not alter the fundamental situation that Capitalists Nos. 1, 2 and 3 are together the exclusive possessors of money, means of production and means of subsistence. Man can only live by producing his own means of subsistence, and he can produce these only if he is in possession of the means of production, of the material conditions of labour. It is obvious from the very outset that the worker who is denuded of the means of production is thereby deprived of the means of subsistence, just as, conversely, a man deprived of the means of subsistence is in no position to create the means of production. Thus even in the first *process*, what stamps money or commodities as *capital* from the outset, even before they have been really transformed into *capital*, is neither their money nature nor their commodity nature, nor the material use-value of these commodities as means of production or subsistence, but the circumstance that this money and this commodity, these means of production and these means of subsistence confront *labour-power*, stripped of all material wealth, as autonomous powers, personified in their owners. The objective conditions essential to the realization of labour are *alienated* from the worker and become manifest as *fetishes* endowed with a will and a soul of their own. *Commodities*, in short, appear as the purchasers of *persons*. The buyer of labour-power is nothing but the personification of *objectified* labour which cedes a part of itself to the worker in the form of the means of subsistence in order to annex the living labour-power for the benefit of the remaining portion, so as to keep itself intact and even to grow beyond its original size by virtue of this annexation. It is not the worker who buys the means of production and subsistence, but the means of production that buy the worker to incorporate him into the means of production.

The *means of subsistence* are a particular form of material existence in which capital confronts the worker before he acquires them through the sale of his labour-power. But by the time the process of production begins the labour-power has already been sold and hence the means of subsistence have passed *de jure* at least into the consumption fund of the worker. These means of subsistence themselves form no part of the labour process, which, apart from the presence of effective labour-power, requires nothing but the materials and means of labour. In fact, of course, the worker must sustain his capacity for work with the aid of means of subsistence, but this, his private consumption, which is at the same time the reproduction of his labour-power, falls outside the process of producing commodities. It is possible that in capitalist production the entire available time of the worker is actually taken up by capital and that the consumption of the means of subsistence is actually no more than an incident in the labour process, like the consumption of coal by the steam-engine, of oil by the wheel, of hay by the horse and like the entire private consumption of the labouring slave. It is in keeping with this that Ricardo, for instance (see note 6 above), lists 'food and clothing' alongside raw materials and tools, as things which 'give effect to labour' and hence serve as 'capital' in the labour process. However that may be
469f *in fact*, the means of subsistence that the worker consumes are commodities that he has *purchased*. As soon as they pass into his hands, and even more evidently, as soon as he has consumed them, they cease to be capital. They form no part of the *physical elements* in which capital manifests itself in the *immediate process of production*, even though they constitute the *physically existing form* of *variable capital* which enters the market place as the purchaser of labour-power within the *sphere of circulation*.[14]

---

[14] This is the valid point underlying Rossi's polemic against the inclusion of the means of subsistence among the components of productive capital. How wide he is of the mark in his interpretation, however, and the extent

When a capitalist takes 500 thalers and invests 400 of them in the means of production and 100 in the acquisition of labour-power, these 100 thalers constitute his *variable* capital. With them the workers buy the means of subsistence, either from the same capitalist or from another. These 100 thalers are nothing but the *money-form* of the means of subsistence which in fact constitute the *physical manifestation* of the variable capital. Within the *immediate process of production* the variable capital has ceased to exist: it exists neither in the form of money, nor of commodities, but in the form of *living labour* which the capitalist has acquired through the purchase of labour-power. And it is only by virtue of this transformation of variable capital into labour that the quantum of value invested in money or commodities can be converted into *capital.* Thus when we look at the process of capitalist production as a *whole* and not merely at the immediate production of commodities, we find that although the *sale and purchase of labour-power* (which itself conditions the transformation of a part of the capital into variable capital) is entirely separate from the immediate production process, and indeed precedes it, it yet forms the *absolute foundation* of capitalist production and is an integral *moment* within it. Material wealth transforms itself into capital simply and solely because the worker sells his labour-power in order to live. The *articles* which are the material conditions of labour, i.e. the *means of production,* and the articles which are the precondition for the survival of the worker himself, i.e. the *means of subsistence,* both become *capital* only because of the phenomenon of *wage-labour.* Capital is not a *thing,* any more than money is a *thing.* In capital, as in money, certain *specific social relations of production between people* appear as *relations of things to people,* or else certain social relations appear as the *natural properties of things in society.* Without a *class dependent on wages,* the moment individuals confront each other as free persons, there can be no production of surplus-value; without the production of surplus-value there can be no capitalist production, and hence no capital and no capitalist! Capital and wage-labour (it is thus we designate the labour of the worker who sells his own labour-power) only express two aspects

---

of the confusion introduced by his rationalizations, is something we shall return to in a later chapter.*

*This point is dealt with in *Grundrisse,* pp. 591–4. Marx did not however return to it anywhere in *Capital,* or in *Theories of Surplus-Value.*

of the self-same relationship. Money cannot become capital unless it is exchanged for labour-power, a commodity sold by the worker himself. Conversely, work can only be wage-labour when its *own* material conditions confront it as autonomous powers, alien property, value existing for itself and maintaining itself, in short as capital. If capital in its material aspect, i.e. in the use-values in which it has its being, must depend for its existence on the material conditions of labour, these material conditions must equally, on the formal side, confront labour as *alien, autonomous powers*, as value – objectified labour – which treats living labour as a mere means whereby to maintain and increase itself. Thus wage-labour, the wages system, is a social form of work indispensable to capitalist production, just as capital, i.e. potentiated value, is an indispensable social form which must be assumed by the material conditions of labour in order for the latter to be wage-labour. Wage-labour is then a necessary condition for the formation of capital and remains the essential prerequisite of capitalist production. Therefore, although the primary process, the exchange of money for labour-power, or the sale of labour-power, does not as such enter the immediate process of production, it does enter into the production of the relationship as a whole.[15]

As we have seen, the first process, the sale and purchase of labour-power, presupposes that the means of production and subsistence have become autonomous objects confronting the worker, i.e. it presupposes the *personification* of the means of production and subsistence which, as purchasers, negotiate a contract with the workers as vendors. When we leave this process which is enacted in the *market-place*, in the *sphere of circulation*, and proceed directly to the *immediate process of production*, we find that it is primarily a *labour process*. In the labour process the worker enters as worker into a normal active relationship with the means of production determined by the nature and the purpose of the work itself. He takes possession of the means of production and handles them simply as the means and materials of his work. The autonomous nature of these means of production, the way they hold fast 469g to their independence and display a mind of their own, their separation from labour – all this is now *abolished* [*aufgehoben*] in practice. The material conditions of labour now enter into a normal unity with labour itself; they form the material, the organs requisite for its creative activity. The worker treats the hide he is tanning simply as the object of his creative activity, and not as capital. He does not tan the hide for the capitalist.[16] If we consider production just as a labour process, the worker consumes the means of production as the *mere means of subsistence of labour*. But production is also a process of *valorization*, and here the capitalist devours the labour-power of the worker, or appropriates his living labour as the life-blood of capitalism. Raw materials and the object of labour in general exist only to *absorb* the work of others, and the instrument of labour serves only as a conductor, an agency, for this *process of absorption*. By incorporating living labour-power into the material constituents of capital, the latter becomes an animated monster and it starts to act 'as if consumed by love'.* Since work creates value only in a definite useful form, and since every particular useful form of work requires materials and instruments with specific use-values, spindles and cotton, etc. for spinning, hammer, anvil and iron for forging metal, etc., labour can only be drained off if capital assumes the shape of the means of production required for the particular labour process in question, and only in this shape can it annex living labour. This is the reason, then, why the capitalist, the worker and the political economist,

---

[15] We may readily deduce what an F. Bastiat understands about the nature of capitalist production when he declares the wages system to be an external and irrelevant formality in capitalist production, and discovers the truth '*que ce n'est pas la* forme de remunération *qui crée pour lui* (*l'ouvrier*) *cette dépendance*' ['it is not the *form of remuneration* that creates his (the worker's) dependence'] (*Harmonies économiques*, Paris, 1851, p. 378). This is a discovery – and moreover a piece of misinterpreted plagiarism taken over from real economists – altogether worthy of the eloquent ignoramus who discovered in the same work, i.e. in 1851 '*ce qui est plus décisif et infaillible encore, c'est* la disparition des grandes crises industrielles *en Angleterre*' ['what is still more decisive and incontestable is the *disappearance of major industrial crises* in England'] (p. 396). Although F. Bastiat had eliminated great crises from England by decree as early as 1851, England enjoyed a great crisis no later than 1857, and, as we can read in the official reports of the English Chambers of Commerce, a further industrial crisis of hitherto unprecedented dimensions was averted in 1861 only by the outbreak of the American Civil War.

[16] 'We see further from the explanations of the economist himself, that *in the process of production*, capital, the result of labour, is immediately transformed again into the substratum, into the material of labour; and how therefore the momentarily postulated *separation of capital from labour* is immediately *superseded by the unity of both*' (F. Engels, *Deutsch-französische Jahrbücher, etc.*, p. 99) [English translation, p. 430].

---

* Goethe, *Faust*, Part I, Auerbach's Cellar, line 2141.

who is only capable of conceiving the labour process as a process owned by capital, all think of the *physical* elements of the labour process as *capital* just because of their physical characteristics. This is why they are incapable of detaching their physical existence as mere elements in the labour process from the *social* characteristics amalgamated with it, which is what really make them *capital.* They are unable to do this because in reality the labour process that employs the physical qualities of the means of production as the means of subsistence of labour is identical with the labour process that converts these self-same means of production into means for living labour. In the labour process looked at purely for itself the worker utilizes the means of production. In the labour process regarded also as a capitalist process of production, the means of production utilize the worker, so that work appears only as an instrument which enables a specific *quantum of value*, i.e. a specific mass of *objectified* labour, to suck in living labour in order to sustain and increase itself. Regarded thus, the labour process is the *self-valorization process* of objectified labour through the agency of living labour.[17] *Capital* utilizes the *worker*, the *worker* does not utilize *capital*, and only *articles which utilize the worker* and hence possess *independence*, a consciousness and a will of their own in the capitalist, are *capital*.[18]

---

[17] 'Labour is the *agency* by which capital is made productive of ... profit' (John Wade, op. cit., p. 161). 'In bourgeois society, living labour is but a means to increase accumulated labour' (*Manifesto of the Communist Party*, 1848, p. 12) [see *The Revolutions of 1848*, Pelican Marx Library, 1973, p. 81].

[18] The fact that the *means of subsistence* have the particular *economic* characteristic that they purchase workers, or that the *means of production*, such as leather and lasts, *utilize cobbler's assistants* – this inversion of *person and thing* has become an inseparable part of the *physical* character of the elements of production both in capitalist production itself and in the imagination of the economists. So much so in fact that when Ricardo, for example, deems it necessary to give an analysis of the physical elements of capital, he *naturally* without scruples or reflection of any kind makes use of the *correct* economic expressions. Thus he talks of 'capital, or the *means of employing labour*' (i.e. not 'means employed by labour' but 'means of employing labour') (op. cit., p. 92); 'quantity of labour employed by a capital' (ibid., p. 419); 'the fund which is to employ them' (the labourers) (p. 252, etc.). Likewise in modern German the capitalist, the personification of *things* which take labour, is called an '*Arbeitgeber*' [employer, literally a giver of work], while the actual worker who gives his labour is called an '*Arbeitnehmer*' [employee, literally a taker of work]. 'In bourgeois society capital is independent and has individuality, while the living person is dependent and has no individuality' (*Manifesto of the Communist Party*, op. cit.).

Since the labour process is only the instrument and the actual form of the *valorization process*, i.e. since its purpose is to employ the labour materialized in wages to objectify in commodities an *extra quantity of unpaid labour, surplus-value,* i.e. to *create surplus-value,* the crux of the entire process is the exchange of *objectified labour* for *living labour,* of less *objectified labour* for more *living labour.* In the course of the exchange an amount of labour objectified in money as a commodity is exchanged for an equal amount of labour objectified in living labour.

In accordance with the laws of commodity exchange equivalent values change hands, i.e. *equal amounts* of objectified labour, although the one amount is objectified in a thing, the other in flesh and blood. But this exchange only inaugurates the *process of production* through whose agency in fact more labour in living form is given up than was supplied in its objectified form. It is therefore greatly to the credit of the classical economists that they portrayed the entire process of production in terms of a commerce between *objectified* and *living labour,* and that they accordingly defined capital only as *objectified labour* in contrast to living labour. That is to say, they depict capital as *value* which makes use of living labour to *valorize* itself. Their only failings are firstly that they were unable to show how this exchange of more living labour for less objectified labour could be reconciled with the laws of commodity exchange and the definition of the value of commodities in terms of labour-time. And this led to their second failure of confusing the exchange of a definite quantity of *objectified labour* for labour-power in the *process of circulation,* with what takes place in the process of production, namely, the drawing off of living labour by labour *objectified* in the means of production. They confound the *exchange process* that takes place between variable capital and labour-power with the process in which living labour finds itself sucked up and absorbed by constant capital. This failure, too, is rooted in their 'capitalist' blinkers, since for the capitalist himself, who pays for labour only after it has been valorized, the exchange of a small amount of objectified labour for a large amount of living labour appears to be a *single unmediated process.* Therefore, when the modern economist contrasts capital as *objectified labour* to living labour, what he understands by objectified labour is not *products of labour* in the sense that they have a use-value and embody certain useful acts of labour, but *products of labour* in the sense that they are the material base of a certain *amount* of general social labour and hence *value*, money that valorizes itself by acquiring the *living* labour of others. This process of acquisition is mediated by the exchange that takes place in the open market between variable capital and labour-power, but is only completed in the actual process of production.[19]

The subordination of the labour process to capital does not at first affect the actual mode of production and its only practical effects are these: the worker bows to the command, the direction and the supervision of the capitalist, although naturally only in

[19] Immediate labour and objectified labour, labour present and past, living and hoarded labour, etc., all these are forms which the economists use to express the relations of capital and labour. 'Labour and capital... the one *immediate* labour ... the other *hoarded labour*' (James Mill, *Elements of Political Economy*, London, 1821, p. 75). *'Antecedent labour* (capital) ... *present labour'* (E. G. Wakefield in his edition of Adam Smith, London, 1835, Vol. 1, p. 231, note). *'Accumulated labour* (capital) . . . *immediate labour*' (Torrens, op. cit., Ch. 1, p. 31). *'Labour* and *Capital*, that is, *accumulated labour*' (Ricardo, op. cit., p. 499). 'The *specific* advances of the capitalist do not consist of cloth' (or of any use-values as such), 'but of *labour*' (Malthus, *The Measure of Values, etc.*, London, 1823, pp. 17–18).

'Comme tout homme est forcé de consommer avant de produire, l'ouvrier pauvre se trouve dans la dépendance *du riche, et ne peut ni vivre ni travailler, s'il n'obtient de lui des denrées et des marchandises existantes, en retour de celles qu'il promet de produire par son travail... pour l'y* (*id est le riche*) *faire consentir, il a fallu convenir que toutes les fois qu'il échangerait du* travail fait *contre du* travail à faire, *le dernier aurait une valeur supérieure au premier'* ['Just as everyone is forced to consume before he produces, the poor worker finds himself in a state of *dependence* upon the rich man and can neither live nor work without obtaining existing produce and commodities from him, in exchange for those which he pledges to produce by his own labour ... to induce him (i.e. the rich man) to consent to this, it was necessary to agree that whenever *labour already performed* was exchanged for *labour yet to be done*, the latter would be worth more than the former'] (Sismondi, *De la richesse commerciale*, Paris, 1803, Vol. 1, pp. 36–7).

Herr W. Roscher, who evidently has not the faintest idea what the English economists are saying and who has belatedly recollected that Senior christened capital 'abstinence', has the following professorial comment to make, a comment remarkable incidentally for its grammatical 'dexterity': 'The school of Ricardo is also wont to subsume capital under the concept of labour, under the heading of "hoarded labour". This is *inept* because of course (!) the owner of capital has surely (!) done *more* (!) than merely (!) producing (!) and maintaining (!) it; he abstains namely from enjoying it himself, in return for which he requires e.g. interest' (W. Roscher, op. cit.)*. [The 'dexterity' which Marx mentions is a reference to Roscher's play on '*Er*haltung' (maintaining) and '*Ent*haltung' (abstaining).]

*See above p. 314, n. 3.

respect of his labour which belongs to capital. The capitalist makes sure that he wastes no time and sees to it, for example, that he hands over the product of an hour's work every hour, that he only spends the average labour-time necessary for producing the product. Since the relations of capital are essentially concerned with controlling production and since therefore the worker constantly appears in the market as a seller and the capitalist as a buyer, the labour process itself is *continuous* for the most part. It is not interrupted as it would be if the worker were an independent producer of commodities, who depended on selling his wares to individual customers, because the minimum capital must be large enough to occupy the worker continuously and to ensure that there is no necessity to sell the goods in a hurry.[20] Lastly, the capitalist forces the workers to extend the duration of the labour process as far as possible beyond the limits of the labour-time needed to reproduce the amount paid in wages, since it is just this *excess labour* that supplies him with the *surplus-value*.[21]

[20] 'If in the progress of time a change takes place in their (i.e. the workmen's) economic position, if they become the workmen of a capitalist who advances their wages beforehand, two things take place. First, they can now labour continuously; and, secondly, an agent is provided, whose office and whose interest it will be, to see that they *do* labour continuously . . . Here, then, is an increased continuity in the labour of all this class of persons. They labour daily from morning to night, and are not interrupted by waiting for or seeking the customer . . . But the continuity of labour, thus made possible, is secured and improved by the superintendence of the capitalist. He has advanced their wages; he is to receive the produce of their labour. It is his interest and his privilege to see that they do not labour interruptedly or dilatorily' (R. Jones, *Textbook, etc.*, pp. 37 ff. passim).

[21] *'Un axiome généralement admis par les économistes est que tout travail doit laisser un excédant. Cette proposition est pour moi d'une vérité universelle et absolue: c'est le corollaire de la loi de la proportionalité (!), que l'on peut regarder comme le sommaire de toute la science économique. Mais, j'en demande pardon aux économistes, le principe que* tout travail doit laisser un excédant *n'a pas de sens dans leur théorie, et n'est pas susceptible d'aucune* démonstration' ['An axiom generally admitted by economists is that all labour must leave a surplus. In my opinion this proposition is universally and absolutely true: it is the corollary of the law of proportion, which may be regarded as the summary of the whole of economic science. But, if the economists will permit me to say so, the principle that *all labour must leave a surplus* is meaningless according to their theory, and is not susceptible of any *demonstration*.'] (Proudhon, *Philosophie de la misère*). In my work *Misère de la philosophie. Réponse à la Philosophie de la misère de M. Proudhon*, Paris, 1847, pp. 76–91 [English edition, pp. 78–89], I have shown that M. Proudhon has not the slightest idea what this '*excédant du travail*' is, namely

Just as the commodity owner is interested only in the use-value of a commodity as the depository of its exchange-value, so too the capitalist is interested only in the labour process as the depository and instrument of the valorization process. And within the production process too – in so far as it is a valorization process – the means of production continue to be nothing but monetary value, indifferent towards the particular physical form, the specific use-value in which the exchange-value is clothed. Similarly, labour does not count as productive activity with a specific utility, but simply as value-creating substance, as social labour in general which is in the act of objectifying itself and whose sole feature of interest is its *quantity*. Hence in the eyes of capital each sphere of production is simply a sphere in which capital is invested in order to produce more money, in order to maintain and increase already existing money or to acquire *surplus labour*. In every sphere of production the labour process is different, and so too are the factors in that process. Boots cannot be produced with the aid of spindles, cotton and spinners. But the investment of capital in this or that branch of production, the quantities in which the total capital of society is distributed among the various spheres of production, and lastly the conditions in which it emigrates from one type of production
469j to another – all this is determined by the changing conditions according to the needs of society for the products of this or that industry. That is to say, it is determined by society's need of the use-values of the commodities they create. For although it is only the exchange-value of the product that is paid for, products are only ever bought for their use-value. (Since the immediate product of the process of production is the *commodity*, it is only by finding purchasers for his wares that the capitalist can realize the capital which at the end of the process is located in the *commodity*, i.e. realize the *surplus-value* it contains.)

But capital is in itself indifferent to the *particular* nature of every sphere of production. Where it is invested, how it is invested and

---

the *surplusproduct* in which the surplus labour or unpaid labour of the worker becomes manifest. Since he finds that all labour in fact produces such an '*excédant*' in capitalist production he attempts to explain this fact by reference to some mysterious natural attribute of labour, and to shout his way out of the difficulty with such '*sesquipedalia verba*'* as 'corollaire de la loi de la proportionalité', etc.

* 'Many-syllabled words'.

to what extent it is transferred from one sphere of production to another or redistributed among the various spheres of production – all this is determined only by the greater ease or difficulty of selling the commodities manufactured. In reality the mobility of capital is impeded by obstacles which we cannot consider in the present context. But on the one hand, as we shall see, it creates means by which to overcome obstacles that spring from the nature of production itself, and on the other hand, with the development of the mode of production peculiar to itself, it eliminates all the legal and extra-economic impediments to its freedom of movement in the different spheres of production. Above all it overturns all the legal or traditional barriers that would prevent it from buying this or that kind of labour-power as it sees fit, or from appropriating this or that kind of labour. Furthermore, although labour-power assumes a distinctive form in every particular sphere of production, as a capacity for spinning, cobbling, metal-working, etc., so that every sphere of production requires a capacity for labour that is developed in a specific direction, a *distinctive* capacity for labour, it remains true that the flexibility of capital, its indifference to the particular forms of the labour 469k process it acquires, is extended by capital to the worker. He is required to be capable of the same flexibility or *versatility* in the way he applies his labour-power. As we shall see, the capitalist mode of production itself raises obstacles in the way of its own tendency, but it pushes to one side all *legal* and other *extra-economic* obstructions standing in the way of this versatility.[22] Just as capital, as value valorizing itself, views with indifference the particular physical guise in which labour appears in the labour process, whether as a steam-engine, dung heap or silk, so too the worker looks upon the *particular content* of his labour with equal indifference. His work belongs to capital, it is only the use-value of the commodity that he has sold, and he has only sold it to acquire money and, with the money, the means of subsistence. A change in his mode of labour interests him only because every specific mode of labour requires a different development of his labour-power. If his indifference to the particular content of his work does not give him the power to vary his labour-power to order, he will express his indifference by inducing his replacements, the rising generation, to move from one branch of industry to the next, depending on the state of the market. The more highly capitalist production is developed in a country, the greater the demand will be for *versatility* in labour-power, the more indifferent the worker will be towards the *specific content* of his work and the more fluid will be the movements of capital from one sphere of production to the next. Classical economics regards the versatility of labour-power and the *fluidity* of capital as axiomatic, and it is right to do so, since this is the tendency of capitalist production which ruthlessly enforces its will despite obstacles which are in any case largely of its own making. At all events, in order to portray the laws of political economy in their purity we are ignoring these sources of friction, as is the practice in mechanics where the frictions that arise have to be dealt with in every particular application of its general laws.[23]

---

[22] 'Every man, if not restrained by law, would pass from one employment to another, as the various turns in trade should require' (*Considerations Concerning Taking Off the Bounty on Corn Exported, etc.*, London, 1753, p. 4).

|691 Although capitalist and worker confront each other in the market-place only as *buyer*, money, on the one hand, and *seller*, commodity, on the other, this relationship is coloured in advance by the peculiar content of their dealings. This is particularly true since both sides appear *constantly*, repeatedly in the market-place playing the *same* opposed roles. If we consider the relations of commodity-owners in general in the market-place we see that the same man appears alternately as the buyer and seller of wares.

[23] Nowhere does the fluidity of capital, the versatility of labour and the indifference of the worker to the content of his work appear more vividly than in the United States of North America. In Europe, even in England, capitalist production is still affected and distorted by hangovers from feudalism. The fact that baking, shoemaking, etc. are only just being put on a *capitalist* basis in England is entirely due to the circumstance that English capital cherished feudal preconceptions of 'respectability'. It was 'respectable' to sell Negroes into slavery, but it was not respectable to make sausages, boots or bread. Hence all the machinery which conquers the 'unrespectable' branches of industry for capitalism in Europe comes from America. By the same token, nowhere are people so indifferent to the type of work they do as in the United States, nowhere are people so aware that their labour always produces the same product, money, and nowhere do they pass through the most divergent kinds of work with the same nonchalance. This 'versatility' appears to be a quite distinctive mark of the free worker, in contrast to the working slave, whose labour-power is stable and capable of being employed in a manner determined by local custom. 'Slave labour is eminently defective in point of versatility . . . if tobacco be cultivated, tobacco becomes the sole staple, and tobacco is produced whatever be the state of the market, and whatever be the condition of the soil' (Cairnes, op. cit., pp. 46–7).

The fact that two men differ from each other as buyer and seller is of ever diminishing significance since in the course of time everyone assumes all the roles in the sphere of circulation. Now it is also true that once the worker has sold his labour-power and transformed it into money, he too becomes a buyer, and the capitalists appear to him as the mere sellers of goods. But in his hand money is nothing but a means of circulation. In the actual *commodity-market*, then, it is quite true that the worker, like any other owner of money, is a buyer and is distinguished by that fact alone from the commodity owner as seller. But on the *labour-market*, *money* always confronts him as *capital* in the form of money, and so the owner of money appears as capital personified, as a *capitalist*, and he for his part appears to the owner of money merely as the personification of labour-power and hence of labour, i.e. as a *worker*.[24] The two people who face each other on the market-place, in the sphere of circulation, are not just a *buyer* and a *seller*, but *capitalist* and *worker* who confront each other as *buyer* and *seller*. Their relationship as *capitalist* and *worker* is the precondition of their relationship as *buyer* and *seller*. Unlike the situation in the case of other sellers, the relationship does not arise directly from the nature of commodities. This derives from the fact that no one directly produces the products he needs in order to live, so that each man only produces a single product as a *commodity* which he then sells in order to be able to acquire the products of others. Here, however, we are not concerned with the merely *social division of labour* in which each branch of labour is autonomous, so that, for example, a cobbler becomes a seller of boots but a buyer of leather or bread. What we are concerned with here is the *division* of the *constituents of the process of production* itself, constituents that really belong together. This division leads to the progressive *separation* of these elements and their personification *vis-à-vis* each other, so that *money* as the general form of *objectified labour* becomes the *purchaser* of labour-power, the living source of *exchange-value* and hence of wealth. *Real* wealth (from the standpoint of exchange-value), *money* (from the standpoint of use-value), i.e. the *means of subsistence and the means of production*, make their appearance as persons in opposition to the *possibility* of wealth, i.e. labour-power, which appears as a different person.

---

[24] 'The relation of the manufacturer to his operatives ... is purely economic. The manufacturer is Capital, the operative "Labour"' (F. Engels, *Lage der arbeitenden Klassen, etc.*, p. 329) [English edition, op. cit., p. 302].

469m Since *surplus-value* is the product specific to the production process, what is produced is not just a commodity, but also *capital.* Within the production process labour is transformed into capital. The activity of labour-power, i.e. labour, *objectifies* itself in the course of production and so becomes value. But since the labour has ceased to belong to the worker even before he starts to work, what objectified itself for him is *alien labour* and hence a value, *capital*, independent of his own labour-power. The *product* belongs to the capitalist and in the eyes of the worker it is as much a part of capital as the *elements of production.* On the other hand, an existing amount of value – money – becomes *real* capital only when, in the first place, it begins to realize itself, to become part of a *process*, and this it achieves when the activity of labour-power, namely labour, is incorporated in the production process and becomes its property. And secondly, it must yield *surplus-value* as distinct from its original value, and this in turn is again the product of the objectification of surplus labour.

In the process of production labour becomes *objectified labour*, i.e. capital in opposition to living labour-power, and, in the second place, by absorbing labour into production, by thus appropriating it, the original value becomes value in *process* and hence value that creates surplus-value different from itself. It is only because labour is changed into capital in the course of production that we can say that the original quantum of value valorizes itself, that what was at first *potentially* capital has become *capital in actual fact.*[25]*

*

263 [. . .] i.e. to obtain a higher value from the process of production than the sum of the values invested in it and for it (i.e. the production process) by the capitalist. The production of commodities is

[25] 'They' (the workers) 'exchange their labour' (i.e. their labour-power) 'for corn' (i.e. means of subsistence). 'This constitutes their revenue' (i.e. their individual consumption) '. . . whereas their *labour* has become *capital* for their master' (Sismondi, *Nouveaux Principes*, Vol. 1, p. 90). 'The workers who give up their labour in the process of exchange transform it [the product of the whole year] into *capital*' (ibid., p. 105).

---

*At this point the first interpolated passage, consisting of MS. pp. 469a–469m, breaks off. Following Marx's own directions (see our note on p. 995) it is to be succeeded by a second interpolation which Marx numbered pp. 262–4. Page 262 is missing.

simply a means to this end, as indeed the labour process itself is no more than the instrument of the valorization process – in the sense of the process of creating surplus-value, and not, as previously, in the sense of simply creating value.

This result is brought about only as long as the living labour, which the worker has at his disposal and which therefore is objectified in the product of his labour, is greater than the labour contained in the variable capital or laid out in wages, or, in other words, required in the reproduction of his labour-power. Since the production of surplus-value is the means by which the money invested becomes capital, the origins of capital, like the process of capitalist production itself, are based on two factors in the first instance:

First, the *purchase and sale of labour-power*, an act which falls within the sphere of circulation but which, viewed in the context of *capitalist production as a whole*, is not merely an aspect of it and its precondition, but also its continuous result. This purchase and sale of labour power implies that the objective conditions of labour – i.e. the *means of subsistence* and the *means of production* – are separated from the living labour-power itself, so that the latter becomes the sole property at the disposal of the worker and the sole commodity which he has to sell. This separation is so radical that these conditions of labour appear as *independent persons* confronting the worker, for as their owner the capitalist is merely their personification, in opposition to the worker who is the owner of nothing but his labour-power. This separation and independence is the premiss on the basis of which the sale and purchase of labour-power can proceed and living labour can be absorbed into dead labour as a means of maintaining and increasing it, i.e. of enabling it to valorize itself. Without the *exchange* of variable capital for labour-power the total capital could not valorize itself and so the formation of capital and the transformation of the means of production and means of subsistence into capital could not take place. The second factor then is the actual process of production, i.e. the actual consumption of the labour-power purchased by the owner of money or commodities.*

*The following quotation, the first part of which is missing, occurs in the MS. immediately after the above text, to which it has no relation. It is in fact the continuation of a footnote referring to the missing text on p. 262: '. . . to

264 In the actual process of production the objective conditions of labour – its materials and instruments – serve to ensure not just that living labour objectifies itself, but that *more* labour objectifies itself than was contained in variable capital. They therefore act as the means by which the surplus labour which appears in the form of surplus-value (and surplus produce) is extorted and absorbed. If, therefore, we take the two factors together: first, the exchange of labour-power for variable capital, and second, the process of production proper (in which living labour is incorporated as an *agens** into capital), the entire process has the following characteristics. (1) Less objectified labour is exchanged for more living labour, since what the capitalist receives *realiter* for wages is living labour. And (2) the objective forms in which capital manifests itself directly in the labour process, the means of production (once again: objectified labour), are the instruments by means of which living labour is extorted and absorbed. Thus the entire process is a traffic between objectified and living labour in which living labour is transformed into objectified labour and in which at the same time objectified labour is transformed into capital. So that in the upshot living labour is transformed into capital. Hence the process is one which produces surplus-value and hence *capital*, as well as actual produce. (Cf. pp. 96–108.)†

---

three capital workmen or to four ordinary ones . . . If the three could be hired at £3 10s. apiece, while the four required £3 apiece, though the wages of the three would be higher, the price of the work done by them would be lower. It is true that the causes which raise the amount of the labourers' wages often raise the rate of the capitalist's profit. If, by increased industry, one man performs the work of two, both the amount of wages, and the rate of profits will generally be raised; not by the rise of wages, but *in consequence of the additional supply of labour having diminished its price*, or having diminished the period for which it had previously been necessary to advance that price. The labourer, on the other hand, is principally interested in the *amount of wages*. The amount of his wages being given, it is certainly his interest that the *price of labour should be high*, for on that depends the degree of exertion imposed on him' (op. cit., pp. 14, 5).

And from the same work: 'The labourer's situation does not depend on the amount which he receives at any one time, but on his average receipts during a given period . . . The longer the period taken, the more accurate will be the estimate' (ibid., p. 7). 'The year is the best period to take. It includes both summer and winter wages' (ibid., p. 7).

---

*'Effective force'.

†These figures refer to MS. pp. 469a–469m, i.e. pp. 995–1016 of the present text.

Hence we may say that the means of production appear not just as the means for accomplishing work, but as the means for *exploiting the labour of others.**

*

One further point remains to be made about value or money as the objectification of an average measure of general social labour. If we take spinning, for example, we see that it may be performed at a rate that either falls *below* or rises *above* the social average. That is to say, a certain quantity of spinning may be equal to, greater or less than the same quantity of the average, e.g. it may be the same magnitude (length) as the labour-time objectified in a certain amount of gold. But if the spinning is carried out with a degree of intensity normal in its particular *sphere*, e.g. if the labour expended on producing a certain amount of yarn in an hour = the normal quantity of yarn that an hour's spinning will produce on average in the given social conditions, then the labour objectified in the yarn is *socially necessary labour*. As such it has a quantitatively determinate relation to the social average in general which acts as the standard, so that we can speak of the same amount or a greater or smaller one. It itself therefore expresses a *definite quantum* of average social labour.

THE FORMAL SUBSUMPTION OF LABOUR UNDER CAPITAL

The labour process becomes the instrument of the valorization process, the process of the self-valorization of capital – the manufacture of surplus-value. The labour process is subsumed under capital (it is its *own* process) and the capitalist intervenes in the process as its director, manager. For him it also represents the direct exploitation of the labour of others. It is this that I refer to as the *formal subsumption of labour under capital*. It is the general form of every capitalist process of production; at the same time, however, it can be found as a *particular* form alongside the *specifically capitalist mode of production* in its developed form, because although the latter entails the former, the converse does not necessarily obtain [i.e. the formal subsumption can be found in the absence of the specifically capitalist mode of production].

---

* At this point the second interpolated passage comes to an end. What follows is the continuation of p. 469 of the MS.

470 The process of production has become the process of capital itself. It is a process involving the *factors of the labour process* into which the capitalist's money has been converted and which proceeds under his direction with the sole purpose of using money to make more money.

When a peasant who has always produced enough for his needs becomes a day labourer working for a farmer; when the hierarchic order of guild production vanishes making way for the straightforward distinction between the capitalist and the wage-labourers he employs; when the former slave-owner engages his former slaves as paid workers, etc., then we find that what is happening is that production processes of varying social provenance have been transformed into capitalist production. The changes delineated above then come into force. A man who was formerly an independent peasant now finds himself a factor in a production process and dependent on the capitalist directing it, and his own livelihood depends on a contract which he as commodity owner (viz. the owner of labour-power) has previously concluded with the capitalist as the owner of money. The slave ceases to be an instrument of production at the disposal of his owner. The relationship between master and journeyman vanishes. That relationship was determined by the fact that the former was the master of his craft. He now confronts his journeyman only as the owner of capital, while the journeyman is reduced to being a vendor of labour. Before the process of production they all confront each other as commodity owners and their relations involve nothing but *money*; *within* the process of production they meet as its components personified: the capitalist as 'capital', the immediate producer as 'labour', and their relations are determined by labour as a mere constituent of capital which is valorizing itself.

Furthermore, the capitalist takes good care that the labour adheres to the normal standards of quality and intensity, and he extends its duration as far as possible in order to increase the surplus-value that it yields. The *continuity* of labour increases when producers dependent on individual customers are supplanted by producers who, bereft of wares to sell, have a constant paymaster in the shape of the capitalist.

The mystification inherent in the *capital-relation* emerges at this point. The value-sustaining power of labour appears as the self-supporting power of capital; the value-creating power of labour as the self-valorizing power of capital and, in general, in accordance with its concept, *living* labour appears to be put to work by *objectified* labour.

All this notwithstanding, this change does not in itself imply a fundamental modification in the real nature of the labour process, the actual process of production. On the contrary, the fact is that capital subsumes the labour process as it finds it, that is to say, it takes over an *existing labour process*, developed by different and more archaic modes of production. And since that is the case it is evident that capital took over an *available, established labour process*. For example, handicraft, a mode of agriculture corresponding to a small, independent peasant economy. If changes occur in these traditional established *labour processes* after their takeover by capital, these are nothing but the gradual consequences of that subsumption. The work may become more intensive, its duration may be extended, it may become more continuous or orderly under the eye of the interested capitalist, but in themselves these changes do not affect the character of the actual labour process, the actual mode of working. This stands in striking contrast to the development of a *specifically capitalist mode of production* (large-scale industry, etc.); the latter not only transforms the situations of the various agents of production, it also *revolutionizes* their actual mode of labour and the real nature of the labour process as a whole. It is in contradistinction to this last that we come to designate as the *formal subsumption of labour under capital* what we have discussed earlier, viz. the takeover by capital of a mode of labour developed before the emergence of capitalist relations. The latter as a form of *compulsion* by which surplus labour is exacted by extending the duration of labour-time – a *mode of compulsion* not based on personal relations of domination and dependency, but simply on differing economic functions – this is common to both forms. However, the specifically capitalist mode of production has yet other methods of exacting surplus-value at its disposal. But given a pre-existing mode of labour, i.e. an *established* development of the productive power of labour and a mode of labour corresponding to this productive power, surplus-value can be created only by lengthening the working day, i.e. by increasing *absolute surplus-value*. In the *formal* subsumption of labour under capital, this is the *sole* manner of producing surplus-value.

The general features of the labour process as described in

Chapter II,* for example, the sundering of the objective conditions of labour into materials and instruments on the one hand, and the living activity of the workers on the other, are all independent of every historical and specifically social conditioning and they remain valid for all possible forms and stages in the development of the processes of production. They are in fact immutable natural conditions of human labour. This is strikingly confirmed by the fact that they hold good for people who work independently, i.e. for those, like Robinson Crusoe, who work not in exchange with society, but only with nature. Thus they are in fact absolute determinations of *human* labour as such, as soon as it has evolved beyond the purely animal.

The way in which even the merely formal subsumption of labour under capital begins to become differentiated within itself – and does so increasingly as time goes on, even on the basis of the old, traditional mode of labour – is in terms of the *scale* of production. That is to say, differences appear later in the volume of the means of production invested, and in the number of workers under the command of a single employer. For example, what appeared to be the maximum attainable in the mode of production of the guilds (let us say, in reference to the number of journeymen employed) can scarcely serve as a minimum for the relations of capital. For the latter can achieve no more than a nominal existence unless the capitalist can employ at the very least enough workers to ensure that the surplus-value he produces will suffice for his own private consumption and to fill his accumulation fund. Only then will he be relieved of the need to work directly himself and be able to content himself with acting as *capitalist*, i.e. as supervisor and director of the process, as a mere function, as it were, endowed with consciousness and will, of the capital engaged in the process of valorizing itself. This enlargement of *scale* constitutes the real foundation on which the specifically capitalist mode of production can arise if the historical circumstances are otherwise favourable, as they were for instance in the sixteenth century. Of course, it may also occur *sporadically*, as something which does not dominate society, at isolated points within earlier social formations.

The distinctive character of the *formal* subsumption of labour under capital appears at its sharpest if we compare it to situations in which capital is to be found in certain specific, subordinate functions, but where it has not emerged as the direct purchaser of labour and as the immediate owner of the process of production, and where in consequence it has not yet succeeded in becoming the dominant force, capable of determining the form of society as a whole. In India, for example, the capital of the *usurer* advances raw materials or tools or even both to the immediate producer in the form of money. The exorbitant interest which it attracts, the interest which, irrespective of its magnitude, it extorts from the primary producer, is just another name for surplus-value. It transforms its money into capital by extorting unpaid labour, surplus labour, from the immediate producer. But it does not intervene in the process of production itself, which proceeds in its traditional fashion, as it always had done. In part it thrives on the *withering* away of this mode of production, in part it is a means to make it *wither* away, to force it to *eke out* a vegetable existence in the most unfavourable conditions. But here we have *not yet* reached the stage of the formal subsumption of labour under capital. A further example is *merchant's capital*, which commissions a number of immediate producers, then collects their produce and sells it, perhaps making them advances in the form of raw materials, etc., or even money. It is this form that provides the soil from which modern capitalism has grown and here and there it still forms the transition to capitalism proper. Here too we find no formal subsumption of labour under capital. The immediate producer still performs the functions of selling his wares and making use of his own labour. But the transition is more strongly marked here than in the case of the usurer. We shall return later to these forms, both of which survive and reproduce themselves as transitional subforms within the framework of capitalist production.

---

*In Chapter 7 of the present edition.

THE REAL SUBSUMPTION OF LABOUR UNDER CAPITAL OR THE SPECIFIC MODE OF CAPITALIST PRODUCTION

We have demonstrated in detail in Chapter III* the crucial importance of *relative surplus-value.* This arises when the individual capitalist is spurred on to seize the *initiative* by the fact that value = the socially necessary labour-time objectified in the product and that therefore *surplus-value* is created for him as soon as the *in-*

---

*Presumably Part Four of the present edition.

dividual value of his product falls *below* its social value and can be sold accordingly at a price *above* its individual value. With the production of relative surplus-value the entire real form of production is altered and a *specifically capitalist form of production* comes into being (at the technological level too). Based on this, and simultaneously with it, the corresponding *relations of production* between the various agents of production and above all between the capitalist and the wage-labourer, come into being for the first time.

The *social* productive forces of labour, or the productive forces of directly social, *socialized* (i.e. collective) labour come into being through co-operation, division of labour within the workshop, the use of *machinery*, and in general the transformation of production by the conscious *use* of the sciences, of mechanics, chemistry, etc. for specific ends, technology, etc. and similarly, through the enormous increase of *scale* corresponding to such developments (for it is only socialized labour that is capable of applying the *general* products of human development, such as mathematics, to the immediate processes of production; and, conversely, progress in these sciences presupposes a certain level of material production). This entire development of the productive forces of *socialized labour* (in contrast to the more or less isolated labour of individuals), and together with it the *use of science* (the *general* product of social development), in the *immediate process of production*, takes the form of the *productive power of capital*. It does not appear as the productive power of labour, or even of that part of it that is identical with capital. And least of all does it appear as the productive power either of the individual worker or of the workers joined together in the process of production. The mystification implicit in the relations of capital as a whole is greatly intensified here, far beyond the point it had reached or could have reached in the merely formal subsumption of labour under capital. On the other hand, we here find a striking illustration of the historic significance of capitalist production in its specific form – the transmutation of the immediate process of production itself and the development of the social forces of production of labour.

It has been shown (Chapter III)* how not merely at the level of ideas, but also in reality, the social character of his labour confronts the worker as something not merely alien, but hostile and antagonistic, when it appears before him objectified and personified in capital.

---

*Presumably Part Three, in this case.

If the production of absolute surplus-value was the material expression of the formal subsumption of labour under capital, then the production of relative surplus-value may be viewed as its real subsumption.

At any rate, if we consider the two forms of surplus-value, absolute and relative, separately, we shall see that absolute surplus-value always precedes relative. To these two forms of surplus-value there correspond two separate forms of the subsumption of labour under capital, or two distinct forms of capitalist production. And here too one form always precedes the other, although the second form, the more highly developed one, can provide the foundations for the introduction of the first in new branches of industry.

ADDITIONAL REMARKS ON THE FORMAL SUBSUMPTION OF LABOUR UNDER CAPITAL

Before proceeding to a further examination of the real subsumption of labour under capital, here are a few additional reflections from my notebooks.

The form based on absolute surplus-value is what I call the *formal subsumption of labour under capital*. I do so because it is only *formally* distinct from earlier modes of production on whose foundations it arises spontaneously (or is introduced), either when the producer is self-employing or when the immediate producers are forced to deliver surplus labour to others. All that changes is that compulsion is applied, i.e. the method by which surplus labour is extorted. The essential features of *formal subsumption* are:

1. The pure money relationship between the man who appropriates the surplus labour and the man who yields it up: subordination in this case arises from the *specific content* of the sale – there is not a subordination underlying it in which the producer stands in a relation to the exploiter of his labour which is determined not just by money (the relationship of one commodity owner to another), but, let us say, by political constraints. What

brings the seller into a relationship of dependency is *solely* the fact that the buyer is the owner of the conditions of labour. There is no fixed political and social relationship of supremacy and subordination.

2. This is implicit in the first relationship – for were it not for this the worker would not have his labour-power to sell: it is that his *objective conditions of labour* (the means of production) and the *subjective conditions of labour* (the means of subsistence) confront him as *capital*, as the monopoly of the buyer of his labour-power. The more completely these *conditions of labour* are mobilized against him as alien property, the more effectively the *formal* relationship between capital and wage-labour is established, i.e. the more effectively the formal subsumption of labour under capital is accomplished, and this in turn is the premiss and precondition of its *real* subsumption.

There is no change as yet in the mode of production itself. *Technologically speaking*, the *labour process* goes on as before, with the proviso that it is now *subordinated* to capital. Within the production process, however, as we have already shown, two developments emerge: (1) an *economic* relationship of supremacy and subordination, since the consumption of labour-power by the capitalist is naturally supervised and directed by him; (2) labour becomes far more continuous and intensive, and the conditions of labour are employed far more economically, since every effort is made to ensure that no more (or rather even less) *socially necessary* time is consumed in making the product – and this applies both to the living labour that is used to manufacture it and to the *objectified* labour which enters into it as an element in the means of production.

With the *formal* subsumption of labour under capital the *compulsion* to *perform surplus labour*, and to create the *leisure time* necessary for development independently of material production, differs only in form from what had obtained under the earlier mode of production. (Even though, be it noted, this compulsion implies also the necessity of forming needs, and creating the means of satisfying them, and of supplying quantities of produce well in excess of the traditional requirements of the worker.) But this formal change is one which increases the continuity and intensity of labour; it is more favourable to the development of *versatility among the workers*, and hence to increasing diversity in modes of working and ways of earning a living. Lastly, it dissolves the relationship between the owners of the conditions of labour and the workers into a *relationship of sale and purchase, a purely financial relationship*. In consequence the process of exploitation is stripped of every patriarchal, political or even religious cloak. It remains true, of course, that the *relations of production* themselves create a new relation of *supremacy and subordination* (and this also has a *political* expression). But the more capitalist production sticks fast in this formal relationship, the less the relationship itself will evolve, since for the most part it is based on small capitalists who differ only slightly from the workers in their education and their activities.

474 The variations which can occur in the relation of *supremacy and subordination* without affecting the mode of production can be seen best where *rural* and *domestic* secondary industries, undertaken primarily to satisfy the needs of individual families, are transformed into autonomous branches of capitalist industry.

The distinction between labour *formally* subsumed under capital and previous modes of labour becomes more apparent, the greater the increase in the *volume of capital* employed by the individual capitalist, i.e. the greater the increase in the *number of workers employed by him at any one time*. Only with a certain minimum capital does the capitalist cease to be a worker himself and [begin] to concern himself entirely with directing work and organizing sales. And the *real* subsumption of labour under capital, i.e. *capitalist production proper*, begins only when capital sums of a certain magnitude have directly taken over control of production, either because the merchant turns into an industrial capitalist, or because larger industrial capitalists have established themselves on the basis of the *formal subsumption*.[26]

If supremacy and subordination come to take the place of slav-

[26] [The text of this footnote is to be found on an extra unnumbered sheet added subsequently. Since the passage to which the footnote refers was followed on the MS. p. 474 by another short paragraph, Marx preceded the footnote with the remark: '(a) This (a) refers not to the last passage, but to the preceding one.' This comment is followed by the footnote itself:]

474a (a) 'A free labourer has generally the liberty of changing his master: this liberty distinguishes a slave from a free labourer, as much as an English man-of-war sailor is distinguished from a merchant sailor . . . The condition of a labourer is superior to that of a slave, because a labourer *thinks* himself *free*; and this conviction, however erroneous, has no small influence on the character of a population' (T. R. Edmonds, *Practical, Moral and Political* ery, serfdom, vassallage and other patriarchal forms of subjection, the change is *purely one of form.* The form becomes *freer*, because it is objective in nature, voluntary in appearance, *purely economic.* (Verte.)*

475 Alternatively, supremacy and subordination in the *process of production* supplant an earlier state of *independence*, to be found, for example, in all self-sustaining peasants, farmers who only have

---

Economy, London, 1828, pp. 56–7). 'The motive that drives a free man to work is much more violent than what drives the slave: a free man has to choose between hard labour and *starvation* (check the passage), a slave between . . . and a good whipping' (ibid., p. 56). 'The difference between the conditions of a slave and a labourer under the money system is very inconsiderable; . . . the master of the slave understands too well his own interest to weaken his slaves by stinting them in their food; but the master of a free man gives him as little food as possible, because the *injury done to the labourer does not fall on himself alone, but on the whole class of masters*' (ibid.).

'In antiquity, *to make mankind laborious beyond their wants*, to make one part of a state work, to *maintain the other part gratuitously*', was only to be achieved through slaves: hence slavery was introduced generally. 'Slavery was then as necessary towards multiplication, as it would now be destructive of it. The reason is plain. *If mankind be not forced to labour, they will only labour for themselves*; and if they have few wants, there will be few who labour. But when states come to be formed and have occasion for idle hands to defend them against the violence of their enemies, food at any rate must be procured for those *who do not labour*; and as by the supposition, the wants of the labourers are small, a method must be found to *increase their labour above the proportion of their wants*. For this purpose *slavery* was calculated . . . The slaves were forced to labour the soil which fed both them and the idle freemen, as was the case in Sparta; or they filled all the servile places which freemen fill now, and they were likewise employed, as in Greece and in Rome, in supplying with manufactures those whose service was necessary for the state. Here then was a *violent method of making mankind laborious* in raising food . . . Men were then forced to labour, because *they were slaves to others*; men are now forced to labour because they are *slaves of their own wants*' (J. Steuart, Dublin edition, Vol. 1, pp. 38–40).

In the sixteenth century, the same Steuart says, 'while on the one hand the lords dismissed their retainers, the farmers' (who were transforming themselves into industrial capitalists) 'dismissed the idle mouths. From a *means of subsistence* agriculture was transformed into a *trade*.' The consequence was, 'The withdrawing . . . of a number of hands from a trifling agriculture *forces* in a manner, the *husbandmen to work harder*; and *by hard labour upon a small spot, the same effect* is produced as *with slight labour upon a great extent*' (ibid., p. 105).

---

* This refers to the remark quoted in footnote 26.

to pay a rent on what they produce, either to the state or a landlord; rural or domestic secondary industry or *independent handicraft*. Here then we encounter the loss of an earlier *independence* in the process of production, and the relation of supremacy and subordination is itself the result of the rise of capitalist production.

Lastly, the relation of capitalist and wage-labourer can replace that of the guild master and his journeyman and apprentices, a situation found to some extent in urban manufacture. The *medieval guild system*, of which analogous forms were developed to a limited extent in both Athens and Rome, and which was of such crucial importance in Europe for the evolution of both capitalists and free labourers, is a *limited* and as yet inadequate form of the relationship between capital and wage-labour. It involves relations between buyers and sellers. Wages are paid and masters, journeymen and apprentices encounter each other as free persons. The technological basis of their relationship is *handicraft*, where the more or less sophisticated use of *tools* is the decisive factor in production; independent personal labour, and hence its professional development, which requires a longer or shorter spell as an apprentice–these are what determine the results of labour. The master does indeed own the conditions of production – tools, materials, etc. (although the tools may be owned by the journeyman too) – and he owns the product. To that extent he is a *capitalist*. But it is not as capitalist that he is *master*. He is an *artisan* in the first instance and is supposed to be a master of his craft. Within the process of production he appears as an artisan, like his journeymen, and it is he who initiates his apprentices into the mysteries of the craft. He has precisely the same relationship to his apprentices as a professor to his students. Hence his approach to his apprentices and journeymen is not that of a capitalist, but of a *master* of his craft, and by virtue of that fact he assumes a position of superiority in the corporation and hence towards them. It follows that his capital is restricted in terms of the *form it assumes*, as well as in *value*. It is far from achieving the freedom of capital proper. It is not a *definite quantum of objectified labour*, value in general, at liberty to assume this or that form of the conditions of labour depending on the form of living labour it acquires in order to produce surplus labour. Before he can invest money in *this particular* branch of trade, in his own craft, before he can set about purchasing either the objective conditions of labour, or acquiring the necessary journeymen and apprentices, he has to pass through the prescribed stages of apprentice and journeyman and even produce his own masterpiece. He can transform money into capital only in his own craft, i.e. not merely as the means of his own labour, but as the means of exploiting the labour of others. His capital is bound to a definite kind of *use-value* and hence does not confront his own workers directly as *capital*. The methods of work that he employs are laid down not just by tradition, but by the guild – they are thought of as indispensable, and so, from this point of view too, it is the use-value of labour, rather than its exchange-value, that appears to be the ultimate purpose. It does not remain at the discretion of the master to produce work of this or that standard; all the arrangements of the guild are designed to ensure that work of a *definite quality* is produced. He has as little control over the price as over the methods of work. The *restrictions* that prevent his wealth from functioning as capital also ensure that this capital does not exceed a certain *maximum*. He may not employ more than a *certain number* of journeymen, since the guild guarantees that all the masters earn a certain amount from their trade. Lastly, there is the relationship of the master to the other masters in the guild. As a master he belonged to a corporation which [enforced] certain collective conditions of production (guild restrictions, etc.) and possessed political rights, a share in municipal administration, etc. He worked to order – with the exception of what he produced for merchants – and produced goods for immediate use. The number of masters too was restricted as a result. He did not confront his workers *merely as a merchant*. Even less could the merchant convert his money into productive capital; he could only 'commission' the goods, not produce them himself. Not exchange-value as such, not enrichment as such, but a life appropriate to a certain *status or condition* – this was the purpose and result of the exploitation of the labour of others. The *instrument* of labour was the crucial factor here. In many trades (e.g. tailoring) the master was supplied with raw materials by his clients. The limits on production were kept by regulation within the limits of actual consumption. That is to say, production was not restricted by the confines of capital itself. In capitalist production these barriers are swept away along with the socio-political limits in which capital was confined. In short, what we see here is not yet *capital* proper.

The purely formal conversion of production based on handicraft into capitalist production, i.e. a change in which for the time being the technological process remains the same, is achieved by the *disappearance of all these barriers.* And this in turn brings about changes in the relations of supremacy and subordination. The master now ceases to be a capitalist because he is a master, and becomes a master because he is a capitalist. The limits on his production are no longer determined by the limits imposed on his capital. His capital (money) can be freely exchanged for labour, and hence the conditions of labour of any kind whatever. He can cease to be an artisan. With the sudden expansion of trade and consequently of the demand for goods on the part of the merchant class, the production of the guilds is driven beyond its limits by its own momentum and hence is converted formally into capitalist production.

Compared to the independent artisan who makes goods for other customers, we observe a great increase in the continuity of labour of the man who works for a capitalist whose production is not limited by the haphazard requirements of isolated customers but only by the limits of the capital that employs him. In contrast to the slave, this labour becomes more productive because more intensive, since the slave works only under the spur of external fear but not for *his existence* which is *guaranteed* even though it does not belong to him. The free worker, however, is impelled by his wants. The consciousness (or better: the *idea*) of free self-determination, of liberty, makes a much better worker of the one than of the other, as does the related feeling (sense) of *responsibility*; since he, like any seller of wares, is responsible for the goods he delivers and for the quality which he must provide, he must strive to ensure that he is not driven from the field by other sellers of the same type as himself. The *continuity in the relations* of slave and slave-owner is based on the fact that the slave is kept in his situation by *direct compulsion.* The free worker, however, must maintain his own position, since his existence and that of his family depends on his ability continuously to renew the sale of his labour-power to the capitalist.

In the eyes of the slave a *minimal wage* appears to be a constant quantity, independent of his work. For the free worker, however, the *value of his labour-power* and the average wage *corresponding to it* does not appear to him as something predestined, as something independent of his own labour and determined by the mere needs of his physical existence. The *average* for the class as a whole remains more or less *constant*, like the value of all commodities; but this is not how it immediately appears to the *individual* worker whose wages may stand above or below this minimum. The *price of labour* sometimes sinks below and sometimes rises above the *value of labour-power.* Furthermore, there is scope for variation (within narrow limits) to allow for the worker's *individuality*, so that partly as between *different* trades, partly in the *same* one, we find that wages vary depending on the diligence, skill or strength of the worker, and to some extent on his actual personal achievement. Thus the size of his wage packet appears to vary in keeping with the results of his own work and its individual quality. This is particularly evident in the case of *piece rates.* Although, as we have shown, the latter do not affect the general relationship between capital and labour, between necessary labour and surplus labour, the result differs for the individual worker, and it does so in accordance with his particular achievement. In the case of the slave, great physical strength or a special talent may enhance his value to a *purchaser*, but this is of no concern to him. It is otherwise with the free worker who is the owner of *his labour-power.*

477 The higher value of his labour-power must accrue to him and it is expressed in the form of higher wages. So there are great variations in the wages paid, depending on whether a particular type of work requires a more highly developed labour-power at greater cost or not. And this gives scope for individual variation while, at the same time, it also provides the worker with an incentive to develop his own labour-power. Certain though it be that the mass of work must be performed by more or less unskilled labour, so that the vast majority of wages are determined by the *value of simple labour-power*, it nevertheless remains open to individuals to raise themselves to higher spheres by exhibiting a particular talent or energy. In the same way there is an abstract possibility that this or that worker might conceivably become a capitalist and the exploiter of the labour of others. The slave is the property of a particular *master*; the worker must indeed sell himself to capital, but not to a particular capitalist, and so within certain limitations he may choose to sell himself to whomever he wishes; and he may also change his master. The effect of all these differences is to make the free worker's work more intensive, more continuous, more

flexible and skilled than that of the slave, quite apart from the fact that they fit him for quite a different historical role. The slave receives the means of subsistence he requires in the form of *naturalia* which are fixed both in kind and quantity – i.e. he receives *use-values.* The free worker receives them in the shape of *money, exchange-value,* the abstract social form of wealth. Even though his wage is in fact nothing more than the *silver* or *gold* or *copper* or *paper* form of the necessary means of subsistence into which it must constantly be dissolved – even though money functions here only as a *means of circulation,* as a vanishing form of exchange-value, that *exchange-value, abstract wealth,* remains in his mind as something more than a particular use-value hedged round with traditional and local restrictions. It is the worker himself who converts the money into whatever use-values he desires; it is he who buys commodities as he wishes and, as the *owner of money,* as the buyer of goods, he stands in precisely the same relationship to the sellers of goods as any other buyer. Of course, the conditions of his existence – and the limited amount of money he can earn – compel him to make his purchases from a fairly restricted selection of goods. But some variation is possible as we can see from the fact that newspapers, for example, form part of the essential purchases of the urban English worker. He can save or hoard a little. Or else he can squander his money on drink. But even so he acts as a free agent; he must pay his own way; he is responsible to himself for the way he spends his wages. *He learns to control himself, in contrast to the slave,* who needs a master. Admittedly, this is valid only if we consider the transformation from serf or slave into free worker. In such cases the capitalist relationship appears to be an improvement in one's position in the social scale. It is otherwise when the independent peasant or artisan becomes a wage-labourer. What a gulf there is between the proud yeomanry of England of which Shakespeare speaks and the English agricultural labourer! Since the sole purpose of work in the eyes of the wage-labourer is his wage, money, a specific quantity of exchange-value from which every particular mark of use-value has been expunged, he is wholly indifferent towards the *content* of his labour and hence his own particular form of activity. While he was in the guild or caste system his activity was a calling, whereas for the slave, as for the beast of burden, it is merely something that befalls him, something forced on him, it is the mere activation of his labour-power. Except where labour-power has been rendered quite one-sided by the division of labour, the free worker is *in principle* ready and willing to accept every possible variation in his labour-power and activity which promises higher rewards (as we can see from the way in which the surplus population on the land constantly pours into the towns). Should the worker prove more or less incapable of this versatility, he still regards it as open to the next generation, and the new generation of workers is infinitely distributable among, and adaptable to, new or expanding branches of industry. We can see this *versatility*, this perfect indifference towards the particular content of work and the free transition from one branch of industry to the next, most obviously in North America, where the development of wage-labour has been relatively untrammelled by the vestiges of the guild system etc. This *versatility* stands in stark contrast to the utterly monotonous and traditional nature of *slave labour*, which does not vary with changes in production, but which requires, on the contrary, that production be adapted to whatever mode of work has once been introduced and carried on from one generation to the next. All American commentators point to this phenomenon as illustrating the distinction between the free labour of the North and the slave labour of the South. (See Cairnes.)* The constant development of *new forms of work*, this continual change – which corresponds to the diversification of use-values and hence represents a real advance in the nature of exchange-value – and in consequence the progressive division of labour in *society as a whole*: all this is the product of the capitalist mode of production. It starts with free production on the basis of the guild and handicraft system wherever this is not thwarted by the ossification of a particular branch of trade.

478 After these additional comments on the *formal subsumption of labour by capital*, we come now to:

THE REAL SUBSUMPTION OF LABOUR UNDER CAPITAL

The general features of the *formal subsumption* remain, viz. the direct *subordination of the labour process to capital*, irrespective of the state of its technological development. But on this foundation there now arises a technologically and otherwise *specific mode of production – capitalist production* – which transforms the nature *of*

---

*See above, p. 1014, n. 23.

the labour process and its actual conditions. Only when that happens do we witness the *real subsumption of labour under capital.*

'*Agriculture for subsistence* . . . changed for *agriculture for trade* . . . the *improvement of the national territory* . . . proportioned to this *change*' (A. Young, *Political Arithmetic*, London, 1774, p. 49, note).

The real subsumption of labour under capital is developed in all the forms evolved by relative, as opposed to absolute surplus-value.

With the real subsumption of labour under capital a complete (and constantly repeated)[27] revolution takes place in the mode of production, in the productivity of the workers and in the relations between workers and capitalists.

With the real subsumption of labour under capital, all the changes in the labour process already discussed now become reality. The *social forces of production* of labour are now developed, and with large-scale production comes the direct application of science and technology. On the one hand, *capitalist production* now establishes itself as a mode of production *sui generis* and brings into being a new mode of material production. On the other hand, the latter itself forms the basis for the development of capitalist relations whose adequate form, therefore, presupposes a definite stage in the evolution of the productive forces of labour.

It has already been noted that a definite and constantly *growing minimum amount of capital* is both the necessary precondition and the constant result of the *specifically* capitalist mode of production. The capitalist must be the owner or proprietor of the means of production on a *social* scale and in quantities that beggar comparison with the possible production of the individual and his family. The *minimum amount of capital* in an industry increases in proportion to its penetration by capitalist methods and the growth in the social productivity of labour within it. Capital must increase the value of its operations to the point where it assumes social dimensions, and so sheds its *individual* character entirely. It is precisely the productivity of labour, the mass of production, of population and of surplus population created by this mode of production that constantly calls new branches of industry into being once labour and capital have been set free. And in these new branches of

---

[27] *Manifesto of the Communist Party* (1848). [*The Revolutions of 1848*, Pelican Marx Library, p. 70.]

industry capital can once more operate on a small scale and pass through the various phases until this new industry too can be operated on a social scale. This process is continuous. At the same
479 time, *capitalist production* has a tendency to take over all *branches of industry* not yet acquired and where only *formal subsumption* obtains. Once it has appropriated agriculture and mining, the manufacture of the principal textiles etc., it moves on to other sectors where the artisans are still *formally* or even genuinely independent. It has already been remarked, in our discussion of machinery, that the introduction of machinery into one industry leads to its introduction into other industries and other branches of the same industry. Thus spinning machines led to power-looms in weaving; machinery in cotton spinning to machinery in the woollen, linen and silk etc. industries. The increased use of machinery in the mines, cotton mills etc. made the introduction of large-scale production in machine tools inevitable. Quite apart from the improved means of transport rendered necessary by large-scale production, it was also only the introduction of machinery in engineering itself – especially the rotary prime movers – which made steamships and railways a possibility and revolutionized the whole of shipbuilding. Large-scale industry hurls such huge masses of people into industries as yet unsubjugated, or creates such relative surplus populations with them as are required to transform handicraft or small formally capitalist workshops into large-scale concerns. Here the following Tory Jeremiad is relevant:

> 'In the good old times, when "Live and let live" was the general motto, every man was contented with one avocation. In the cotton trade, there were weavers, cotton-spinners, blanchers, dyers and several other independent branches, all living upon the profits of their respective trades, and all, as might be expected, contented and happy. By and by, however, when the downward course of trade had proceeded to some extent first one branch was adopted by the capitalist and then another, till in time, the whole of the people were ousted, and thrown up on the market of labour, to find out a livelihood in the best manner they could. Thus, although *no charter* secures to these men the right to be cotton-spinners, manufacturers, printers etc., yet the course of events has invested them *with a monopoly of all* . . . They have become Jack-of-all trades, and as far as the country is concerned in the business, it is

to be feared, they are masters of none' (*Public Economy Concentrated etc.*, Carlisle, 1833, p. 56).

The material result of capitalist production, if we except the development of the *social productive forces of labour*, is to *raise the quantity of production* and *multiply* and *diversify the spheres of production* and their sub-spheres. For it is only then that the corresponding development of the *exchange-value* of the products emerges – as the realm in which they can operate or realize themselves as *exchange-value.*

'*Production for production's sake*' – production as an end in itself – does indeed come on the scene with the *formal subsumption of labour under capital.* It makes its appearance as soon as the immediate purpose of production is to produce *as much surplus-value as possible*, as soon as the exchange-value of the product becomes the deciding factor. But this *inherent* tendency of capitalist production does not become *adequately realized* – it does not become *indispensable*, and that also means *technologically* indispensable – until the *specific mode of capitalist production* and hence the *real subsumption of labour under capital* has become a reality.

480 The latter has already been argued in detail, so that we may be quite brief here. It is a form of production not bound to a level of needs laid down in advance, and hence it does not predetermine the course of production itself. (Its contradictory character includes a *barrier to production* which it is constantly striving to overcome. Hence crises, over-production etc.) This is one side, in contrast to the former mode of production; if you like, it is the positive side. On the other hand, there is the negative side, its contradictory character: production in contradiction, and indifference, to the *producer*. The real producer as a mere means of production, material wealth as an end in itself. And so the growth of this material wealth is brought about in contradiction to and at the expense of the individual human being. *Productivity of labour* in general = the *maximum of profit* with the *minimum of work*, hence, too, goods constantly become cheaper. This becomes a *law*, independent of the will of the individual capitalist. And this law only becomes reality because instead of the scale of production being controlled by existing needs, the quantity of products made is determined by the constantly increasing scale of production dic-

tated by the mode of production itself. Its aim is that the individual product should contain as *much unpaid labour as possible*, and this is achieved only by *producing for the sake of production*. This becomes manifest, on the one hand, as a law, since the capitalist who produces on too small a scale puts more than the socially necessary quantum of labour into his products. That is to say, it becomes manifest as an adequate embodiment of the *law of value* which develops fully only on the foundation of capitalist production. But, on the other hand, it becomes manifest as the desire of the individual capitalist who, in his wish to render this law ineffectual, or to *outwit it* and turn it to his own advantage, reduces the *individual* value of his product to a point where it falls *below* its socially determined value.

Apart from the increase in the minimum amount of *capital necessary for production*, all these forms of production (of relative surplus-value) have one feature in common. This is that the rationalization of *conditions* for many workers co-operating together directly permits economies. And this contrasts with the fragmentation of conditions in small-scale production, since the *effectiveness* of these collective conditions of production does not bring about a proportionate increase in their quantity and *value*. The fact that they are *employed simultaneously and collectively* causes their *relative* value to sink (with reference to the product), however much their absolute value grows.

PRODUCTIVE AND UNPRODUCTIVE LABOUR

I should like to deal with this briefly before taking a further look at the *changed form of capital* resulting from the capitalist mode of production.

Since the immediate purpose and the *authentic product* of capitalist production is *surplus-value, labour is only productive*, and an exponent of labour-power is only a *productive worker*, if it or he creates *surplus-value* directly, i.e. the only productive labour is that which is directly *consumed* in the course of production for the valorization of capital.

Looked at from the simple standpoint of the *labour process*, labour seemed *productive* if it realized itself in a *product*, or rather a commodity. From the standpoint of capitalist production we may add the qualification that labour is productive if it directly valorizes capital, or creates surplus-value. That is to say, it is productive if it is *realized* in a surplus-value without any equivalent for the worker, its creator; it must appear in surplus produce, i.e. an *additional increment of a commodity* on behalf of the monopolizer of the means of labour, the capitalist. Only the labour which posits the variable capital and hence the total capital as $C+\Delta C = C+\Delta v$ is productive. It is therefore labour which directly serves capital as the agency of its *self-valorization*, as means for the production of surplus-value.

The capitalist labour process does not cancel the general definitions of the labour process. It produces both product and commodity. Labour remains productive as long as it objectifies itself in *commodities*, as the unity of exchange-value and use-value. But the labour process is merely a means for the self-valorization of capital. Labour is productive, therefore, if it is converted into *commodities*, but when we consider the individual commodity we find that a certain proportion of it represents *unpaid* labour, and when we take the *mass of commodities as a whole* we find similarly that a certain proportion of that also represents unpaid labour. In short, it turns out to be a product that costs the capitalist nothing.

The *worker* who performs *productive work* is *productive* and the work he performs is productive if it directly creates *surplus-value*, i.e. if it *valorizes* capital.

481 It is only bourgeois obtuseness that encourages the view that capitalist production is production in its absolute form, the unique form of production as prescribed by nature. And only the bourgeoisie can confuse the questions: what is productive labour? and what is a productive worker from the standpoint of capitalism? with the question: what is *productive* labour as such? And they alone could rest content with the tautological answer that all labour is productive if it produces, if it results in a product or some other use-value or in anything at all.

The only productive worker is one whose labour = the *productive consumption* of labour-power – of the bearer of that labour – on the part of capital or the capitalist.

Two things follow from this:

First, with the development of the *real subsumption of labour under capital*, or the *specifically capitalist mode of production*, the *real* *lever* of the overall labour process is increasingly not the individual worker. Instead, *labour-power socially combined* and the various competing labour-powers which together form the entire production machine participate in very different ways in the immediate process of making commodities, or, more accurately in this context, creating the product. Some work better with their hands, others with their heads, one as a manager, engineer, technologist, etc., the other as overseer, the third as manual labourer or even drudge. An ever increasing number of types of labour are included in the immediate concept of *productive labour*, and those who perform it are classed as *productive workers*, workers directly exploited by capital and *subordinated* to its process of production and expansion. If we consider the aggregate *worker*, i.e. if we take all the members comprising the workshop together, then we see that their *combined activity* results materially in an *aggregate* product which is at the same time a *quantity of goods*. And here it is quite immaterial whether the job of a particular worker, who is merely a limb of this aggregate worker, is at a greater or smaller distance from the actual manual labour. But then: the activity of this aggregate labour-power is its *immediate productive consumption by capital*, i.e. it is the self-valorization process of capital, and hence, as we shall demonstrate, the immediate production of surplus-value, the *immediate conversion of this latter into capital.*

Second, the more detailed definition of productive labour follows from the characteristic features of capitalist production as we have described them. In the first place, the owner of labour-power confronts capital or the capitalist, irrationally, as we have seen it expressed, as the *seller* of his property. He is the direct vendor of *living labour, not of a commodity*. He is a *wage-labourer*. This is the *first premiss*. Secondly, however, once this preliminary process (which is really part of circulation) has been initiated, his labour-power, his labour, is directly incorporated into the production process of capital as a *living factor*; it becomes one of its *components*, a variable component, moreover, which partly maintains and partly reproduces the capital values invested. It goes even further; it *augments* them and, through the creation of surplus-value, it transforms them into value valorizing itself, into capital. This labour *objectifies* itself directly during the labour process as a *fluid quantum of value.*

It is possible for the *first condition to be fulfilled and not the second.* A worker can be a wage-labourer, a day labourer etc. This happens whenever the second moment is absent. Every productive worker is a wage-labourer, but not every wage-labourer is a productive worker. Whenever labour is purchased to be consumed as a *use-value*, as a *service* and not to replace the value of variable capital with its own *vitality* and be incorporated into the capitalist process of production – whenever that happens, labour is not productive and the wage-labourer is no productive worker. His work is consumed for its *use-value*, not as *creating exchange-value*; it is consumed unproductively, not productively. Hence the capitalist does not encounter it in his role of capitalist, a representative of capital. The money that he pays for it is *revenue*, not *capital*. Its consumption is to be formulated not as M–C–M, but as C–M–C (the last being the *labour* or *service* itself). The money functions here only as a means of circulation, not as capital.

482 The *services* that the capitalist buys freely or under compulsion (for example from the state) for their use-value are not consumed productively and cannot become *factors of capital*, any more than the *commodities* he buys for his personal consumption. They do not become factors of capital; they are therefore not productive labour and those who carry them out are not *productive workers.*

The more production becomes the production of commodities, the more each person has to, and wishes to, become a *dealer in commodities*, then the more everyone wants to make money, either from a product, or from his *services*, if his product only exists naturally in the form of a service, and this *money-making* appears as the ultimate purpose of activity of every kind.[28] In capitalist production the tendency for all products to be commodities and all labour to be *wage-labour*, becomes absolute. A whole mass of functions and activities which formerly had an aura of sanctity about them, which passed as ends in themselves, which were performed for nothing or where payment was made in roundabout ways (like all the professions, barristers, doctors, in England where the barrister and the physician neither could nor can sue for payment to this very day) – all these become directly converted into *wage-labourers*, however various their activities and *payment* may be.[29] And, on the other hand, their valuation – the *price* of these different *activities* from the prostitute to the king – becomes subject to the *laws that govern the price of wage-labour*. The implications of this last point should be explored in a special treatise on wage-labour and wages, rather than here. Now the fact that with the growth of capitalist production all *services* become transformed into *wage-labour*, and those who perform them into *wage-labourers*, means that they tend increasingly to be confused with the productive worker, just because they share this characteristic with him. This confusion is all the more tempting because it arises from *capitalist production* and is typical of it. On the other hand, it also creates an opening for its apologists to convert the productive worker, simply because he is a wage-labourer, into a worker who only exchanges his *services* (i.e. his labour as a use-value) for *money*. This makes it easy for them to gloss over the specific nature of this 'productive worker' and of capitalist production – as the production of surplus-value, as the self-valorization of capital in which living labour is no more than the agency it has embodied in itself. A soldier is a wage-labourer, a mercenary, but this does not make a productive worker of him.

---

[28] Aristotle. [See above, p. 253, n. 6.]

Further error springs from two sources.

First, within capitalist production there are always certain parts of the productive process that are carried out in a way typical of *earlier modes of production*, in which the relations of *capital and wage-labour* did not yet exist and where in consequence the capitalist concepts of *productive* and unproductive labour are quite inapplicable. But in line with the dominant mode of production, even those kinds of labour which have not been subjugated by capitalism in reality are so in thought. For example, the self-employing worker is his own wage-labourer; his own means of production appear to him in his own mind as capital. As his own capitalist he puts himself to work as wage-labourer. Such anomalies provide welcome opportunities for all sorts of hot air about the difference between productive and unproductive labour.

483 *Second*, certain kinds of *unproductive work* may be incidentally connected to the process of production and their *price* may even enter into the *price of the commodity*. In consequence the money laid out for them may form part of the *capital invested* and the

---

[29] *Manifesto of the Communist Party* (1848). [*The Revolutions of 1848*, ibid.]

labour they require may appear to be labour exchanged not for *revenue* but directly for *capital.*

As an example of this, let us consider *taxes,* the price for government services. But taxes belong to the *faux frais de production** and as far as capitalist production is concerned they are utterly *adventitious* and anything but a necessary, intrinsic phenomenon *resulting* from it. If, for example, all *indirect* taxes are converted into *direct* ones, the taxes will be paid now as before, but they will cease to be capital investment and will instead be the disbursement of *revenue.* The fact that this metamorphosis is possible shows its superficial, external and incidental nature as far as it touches the capitalist process of production. A comparable metamorphosis in productive labour on the other hand would mean the end of the revenue from capital and of capital itself.

Further examples are legal proceedings, contractual agreements, etc. All matters of this sort are concerned with stipulations between commodity owners as buyers and sellers of goods, and have nothing to do with the relations between capital and labour. Those engaged on them may become the wage-labourers of capital; but this does not make productive workers of them.

Productive labour is merely an abbreviation for the entire complex of activities of labour and labour-power within the capitalist process of production. Thus when we speak of *productive labour* we mean *socially determined* labour, labour which implies a quite specific relationship between the buyer and seller of labour. Productive labour is exchanged directly for *money as capital,* i.e. for money which is intrinsically capital, which is destined to function as capital and which confronts labour-power as capital. Thus productive labour is labour which for the worker only reproduces the value of his labour-power as determined beforehand, while as a value-creating activity it valorizes capital and *confronts* the worker with the values so created and transformed into *capital.* The specific relationship between *objectified* and *living* labour that converts the former into capital also turns the latter into *productive labour.*

The specific product of the capitalist process of production, surplus-value, is created only through an exchange with *productive labour.*

---

*'Incidental costs of production'.

What gives it a *specific use-value* for capital is not its particular utility, any more than the particular useful qualities of the product in which it is objectified. Its use to capital is its ability to generate exchange-value (surplus-value).

The capitalist process of production does not just involve the production of commodities. It is a process which absorbs unpaid labour, which makes the means of production into the means for extorting unpaid labour.

From the foregoing it is evident that for *labour to be designated productive*, qualities are required which are utterly unconnected with the *specific content* of the labour, with its particular utility or the use-value in which it is objectified.

484 Hence labour with *the same content* can be either productive or unproductive.

For instance, Milton, who wrote *Paradise Lost*, was an unproductive worker. On the other hand, a writer who turns out work for his publisher in factory style is a productive worker. Milton produced *Paradise Lost* as a silkworm produces silk, as the activation of *his own* nature. He later sold his product for £5 and thus became a merchant. But the literary proletarian of Leipzig who produces books, such as compendia on political economy, at the behest of his publisher is pretty nearly a productive worker since his production is taken over by capital and only occurs in order to increase it. A singer who sings like a bird is an unproductive worker. If she sells her song for money, she is to that extent a wage-labourer or merchant. But if the same singer is engaged by an entrepreneur who makes her sing to make money, then she becomes a productive worker, since she *produces* capital directly. A schoolmaster who instructs others is not a productive worker. But a schoolmaster who works for wages in an institution along with others, using his own labour to increase the money of the entrepreneur who owns the knowledge-mongering institution, is a productive worker. But for the most part, work of this sort has scarcely reached the stage of being subsumed even formally under capital, and belongs essentially to a transitional stage.

On the whole, types of work that are consumed as services and not in products separable from the worker and hence not capable of existing as commodities independently of him, but which are yet capable of being directly exploited in *capitalist* terms, are of microscopic significance when compared with the mass of capitalist production. They may be entirely neglected, therefore, and can be dealt with under the category of wage-labour that is not at the same time productive labour.

It is possible for work of one type (such as gardening, tailoring etc.) to be performed by the same working man either in the service of an industrial capitalist or on behalf of the immediate consumer. He is a wage-labourer or day labourer in either situation, only he is a *productive* worker in the one case and *unproductive* in the other, because in the one he produces capital and in the other not; because in the one case his work is a factor in the self-valorization process of capital and in the other it is not.

A large part of the annual product which is consumed as revenue and hence does not re-enter production as its means, consists of the most tawdry products (use-values) designed to gratify the most impoverished appetites and fancies. As far as the question of productive labour is concerned, however, the nature of these objects is quite immaterial (although obviously the development of wealth would inevitably receive a check if a disproportionate part were to be reproduced in this way instead of being changed back into the means of production and subsistence, to become absorbed once more – productively consumed, in short – into the process of reproduction either of commodities or of labour-power). This sort of productive labour produces use-values and objectifies itself in products that are destined only for unproductive consumption. In their reality, as articles, they have no *use-value* for the process of reproduction. (For they could acquire this only through *metabolism*, through the exchange with productive use-values; but this is only a displacement. Somewhere they must be consumed unreproductively. Other such articles falling into the category of unproductive consumption could, if need be, also function again as capital. More about this in Bk II, Chapter III,* on the process of reproduction. We would make only one comment here in anticipation: ordinary economic theory finds it impossible to utter a single sensible word on the barriers to the production of luxuries even from the standpoint of capitalism itself. The matter is very simple, however, if the elements of the process of reproduction are examined systematically. If the process of reproduction suffers a check, or if its progress, in so far as this is already determined by the natural growth of the population, is held up by the disproportionate diversion of *productive labour* into unreproductive articles, it follows that the means of subsistence or production will not be reproduced in the necessary quantities. In that event it is possible to condemn the manufacture of luxury goods from the standpoint of capitalist production. For the rest, however, luxury goods are absolutely necessary for a mode of production which creates wealth for the non-producer and which therefore must provide that wealth in forms which permit its acquisition only by those who enjoy.)

---

*i.e. Vol. 2, Part Four.

For the worker himself this productive labour, like any other, is simply a means of reproducing the means of subsistence he requires. For the capitalist to whom both the nature of the use-value and the character of the actual concrete labour employed are matters of complete indifference, it is simply *un moyen de battre monnaie, de produire la survalue.**

485 The desire to define *productive* and *unproductive* labour in terms of their *material* content has a threefold source.

(1) The fetishism peculiar to the capitalist mode of production from which it arises. This consists in regarding *economic* categories, such as being a *commodity* or *productive* labour, as qualities inherent in the material incarnations of these formal determinations or categories;

(2) Looking at the labour process as such, labour is held to be *productive* only if it results in a *product* (and since we are concerned here only with material wealth, it must be a material product);

(3) In the *actual* process of reproduction – considering only its *real* moments – there is a vast difference which affects the formation of wealth, between labour which is engaged on articles essential to reproduction and labour concerned purely with luxuries.

(*Example*: It is a matter of complete indifference to me whether I buy a pair of trousers or whether I just buy the cloth and have a tailor's assistant come into my house and pay him for his *services* (i.e. making it up). I buy it from the merchant tailor because it is cheaper. In either case I convert the money I spend into a use-value that forms part of my individual consumption, and that is designed to gratify my individual need, and not into capital. The tailor's assistant performs the identical *service* for me irrespective of whether he works for the merchant tailor, or in my home. On the other hand, when the same tailor's assistant is employed by a merchant tailor the service he performs for that capitalist is that he does 12 hours' work and is paid only for 6. The service he performs, then, is that he does 6 hours' work for nothing. The fact that this transaction is embodied in the action of making trousers only *conceals* its real nature. As soon as he can, the merchant tailor seeks to convert the trousers back into money, i.e. into a form in which the distinctive character of the work of tailoring has totally disappeared, and the service performed becomes embodied in the fact that one thaler has become two.)

---

*'A means of coining money, of producing surplus-value'.

In general, we may say that *service* is merely an expression for the particular use-value of labour where the latter is useful not as an article, but as an activity. *Do ut facias, facio ut facias, facio ut des, do ut des** – all these are interchangeable formulae for the same situation, whereas in capitalist production the *do ut facias* expresses a highly specific relationship between material wealth and living labour. Since, therefore, in this *purchase of services* the specific relation of capital and labour is not contained – it is either obliterated or simply absent – it is naturally the form preferred by Say, Bastiat and Co. to express the *relation of capital and labour*.†

The worker, too, purchases *services* with his money. This is a form of expenditure, but it is no way to turn money into capital.

No one buys medical or legal 'services' as a means of converting the money laid out into capital.

A large proportion of *services* belongs with the costs of consuming produce. Cooks for example.

The distinction between *productive* and *unproductive* labour depends merely on whether labour is exchanged for *money as money* or for *money as capital*. For instance, if I buy *produce* from a self-employing worker, artisan, etc., the category does not enter into the discussion because there is no direct exchange between money and labour of any kind, but only between *money* and *produce*.

In the case of non-material production there are two possibilities, even where it is undertaken purely for the sake of exchange, producing goods, etc:

---

*'I give so that you may do, I do so that you may do, I do so that you may give, I give so that you may give.'

† See above, p. 300, n. 17.

(1) It results in commodities which exist separately from the producer, i.e. they can circulate in the interval between production and consumption as commodities, e.g. books, paintings and all products of art as distinct from the artistic achievement of the practising artist. Here capitalist production is possible only within very narrow limits. Apart from such cases as, say, sculptors who employ assistants, these people (where they are not independent) mainly work for merchant's capital, e.g. booksellers, a pattern that is only transitional in itself and can only lead to a *capitalist mode of production in the formal* sense. Nor is the position altered by the fact that exploitation is at its greatest precisely in these transitional forms.

(2) The product is not separable from the act of producing. Here too the capitalist mode of production occurs only on a limited scale and in the nature of the case it can operate only in certain areas. (I want *the doctor* and not his errand boy.) For example, in teaching institutions the teachers can be no more than wage-labourers for the entrepreneur of the learning factory. Such peripheral phenomena can be ignored when considering capitalist production as a whole.

'*The productive labourer* [is one who] directly increases *his master's wealth*' (Malthus, *Principles of Political Economy*, 2nd edn, London, 1836 [p. 47, note]).

The distinction between *productive* and *unproductive labour* is vital for accumulation since only the exchange for productive labour can satisfy one of the conditions for the reconversion of surplus-value into capital.

As the representative of *productive capital* engaged in the process of self-expansion, the capitalist performs a *productive* function. It consists in the direction and exploitation of productive labour. In contrast to his fellow-consumers of *surplus-value* who stand in no such immediate and active relationship to their production, his class is the *productive* class par excellence. (As the director of the labour process the capitalist performs *productive labour* in the sense that his labour is involved in the total process that is realized in the product.) We are concerned here only with capital within the immediate process of production. The other functions of capital and the agents which it employs within them form a subject to be left for later.

The definition of *productive labour* (and hence of its opposite, *unproductive* labour) is based on the fact that the production of capital is the production of surplus-value and the labour it employs is labour that produces surplus-value.

487 NET AND GROSS PRODUCT

(This fits better perhaps in Bk III, Chapter III.)
Since the purpose of capitalist production (and hence of *productive* labour) is not the existence of the producer, but the production of surplus-value, it follows that all necessary labour which does not produce surplus labour is superfluous and worthless to capitalist production. The same holds good for a nation of capitalists. All *produit brut* [gross produce] which merely reproduces the worker, i.e. which creates no *produit net* [surplus produce] is just as superfluous as the worker himself. Thus workers who were indispensable for the creation of *produit net*, at a certain stage of development, can become superfluous at a more advanced stage of production which has no need of their services. In other words, only the number of people profitable to capitalism is necessary. The same holds good for the nation of capitalists. 'Is not the real interest of a nation similar' to the interest of a private capitalist for whom 'it would be a matter quite indifferent whether his capital would employ a hundred or a thousand men . . . provided his profits on a capital of £20,000 were not diminished below £2,000'? 'Provided its net real income, its rents and profits be the same, it is of no importance whether the nation consists of ten or of twelve millions of inhabitants . . . If five millions of men could produce as much food and clothing as was necessary for ten millions, food and clothing for five millions would be the net revenue. Would it be of any advantage to the country, that to produce this same net revenue, seven millions of men should be required, that is to say, that seven millions should be employed to produce food and clothing sufficient for twelve millions? The food and clothing of five millions would still be the net revenue.'*

Even the philanthropists can have no objection to bring forward against this statement of Ricardo's. For it is always better that of ten million people only 50 per cent should vegetate as pure production-machines for five millions, than that of twelve millions, seven or 58⅓ per cent should vegetate as such.

---

* Ricardo, *On the Principles of Political Economy*, pp. 416–17.

'Of what use in a modern kingdom would be a whole province thus divided (between self-sustaining little farmers as in the first times of ancient Rome), however well cultivated, except for the mere purpose of breeding men, which singly taken, is a most useless purpose' (Arthur Young, *Political Arithmetic, etc.*, London, 1774, p. 47).

Since capitalist production is *essentiellement* the *production of surplus-value,* its aim is *net produce* and that is to say the form of *surplus-produce* in which *surplus-value* is embodied.

All this conflicts with, for example, the antiquated view typical of earlier modes of production according to which the city authorities would, for instance, prohibit inventions so as not to deprive workers of their livelihood. In such a society the worker was an end in himself and appropriate employment was his privilege, a right which the entire order was concerned to maintain. It conflicts, moreover, with the idea of the protectionist system (as opposed to free trade), an idea tinged with nationalism, which holds that industries should be protected since they form the source of income for a mass of people. They should therefore be protected on a national basis against foreign competition. Finally, it conflicts with the view of Adam Smith that, for example, the investment of capital in agriculture is 'more productive' because the same capital provides work for more hands. From the perspective of an advanced form of capitalist production these are all antiquated and erroneous ideas. A large gross product (as far as the variable part of capital is concerned) standing in proportion to a small net product = a reduction in the productive power of labour and therefore of capital.

488 Traditionally, however, all sorts of confused ideas are current in connection with the gross and net product. They stem in part from the Physiocrats (see Book IV), and in part from Adam Smith who still here and there confuses capitalist production with production on behalf of the immediate producers.

The individual capitalist who sends his money abroad and receives 10 per cent interest for it, whereas by keeping it at home he could employ a mass of surplus people, deserves from the standpoint of capitalism to be crowned king of the bourgeoisie. For this man of virtue simply implements the law which distributes capital on the world market, just as it does within the bounds of the domestic market, viz. in tune with the rate of profit yielded by the various spheres of production: it has the effect of balancing them out and regulating production. (It is irrelevant whether the money goes, for instance, to the Tsar of Russia to finance wars against Turkey. In acting thus the individual capitalist only obeys the immanent law, and hence the moral imperative, of capital to produce as much surplus-value as possible.) However, this has no connection with our examination of the immediate process of production.

Furthermore, the contrast is often made between *capitalist* and *non-capitalist production*. For example, agriculture for subsistence in which hands are occupied, is distinguished from agriculture for trade, which places a much greater product on the market and hence allows people formerly engaged in agriculture to recover a net product in manufacturing. But this distinction has no application *within* capitalist production itself.

On the whole, we have seen that the law of capitalist production is to increase constant capital at the expense of variable, that is, to increase surplus-value, net produce. Secondly, net produce is to be increased in relation to the part of the product that replenishes capital, i.e. wages. Now these two things are frequently confused. If the aggregate product is called the gross product, then in capitalist production it grows in relation to the net product; if we call that portion of the product that can be broken down into wages + net produce the net product, then the net product grows in relation to the gross product. Only in agriculture (owing to the conversion of cultivated land into pasture) does the net product often grow at the expense of the gross product (the overall mass of products) in consequence of certain features peculiar to rent which cannot be discussed in this context.

In other respects the theory of the *net product* as the last and highest purpose of production is no more than the brutal but accurate expression of the fact that the *valorization of capital*, and hence the creation of surplus-value without heed to the worker, is the driving force behind capitalist production.

Its loftiest ideal – corresponding to the relative growth of the *produit net* – is the greatest possible reduction of wages, the greatest possible increase in the number of those living off *produit net*.

MYSTIFICATION OF CAPITAL ETC.

Since – within the process of production – living labour has already been absorbed into capital, all the *social productive forces of labour* appear as the *productive forces* of capital, as intrinsic attributes of capital, just as in the case of money, the creative power of labour had seemed to possess the qualities of a thing. What was true of money is even truer of capital because:

(1) although labour is an *expression of labour-power*, although it represents the effort of the *individual worker*, and so belongs to him (it is the substance with which he pays the capitalist for what he receives from him), it nevertheless objectifies itself in the product and so belongs to the capitalist. – Even worse, the *social configuration* in which the individual workers exist, and within which they function only as the particular organs of the total labour-power that makes up the workshop as a whole, does not belong to them either. On the contrary, it confronts them as a *capitalist arrangement* that is *imposed* on them;

(2) these *social productive forces of labour*, or *productive forces of social labour*, came into being historically only with the advent of the specifically capitalist mode of production. That is to say, they appeared as something intrinsic to the relations of capitalism and inseparable from them;

(3) with the development of the capitalist mode of production the *objective conditions of labour* take on a different form owing to the scale on which, and the economy with which, they are employed (quite apart from the form of the machinery itself). As they develop they become increasingly concentrated; they represent *social* wealth and, to put the matter in a nutshell, their scope and their effect is that of the *conditions of production* of labour *socially* combined. And quite apart from the combination of labour, the *social character of the conditions of labour* – and this includes machinery and *capitale fixe* of every kind – appears to be entirely autonomous and independent of the worker. It appears to be a *mode of existence of capital* itself, and therefore as something ordered by *capitalists* without reference to the workers. Like the *social character* of their own labour, but to a far greater extent, the *social character* with which the conditions of production are en-

dowed, as the conditions of production of the combined labour of the *community*, appears as *capitalistic*, as something independent of the workers and intrinsic to the conditions of production themselves.

ad (3) we should at once add the following rider which to some extent anticipates later discussion:

Profits as distinct from surplus-value can rise as a result of the economical use of *collective* conditions of labour, such as saving in overheads, for example heating, lighting, etc. The fact that the value of the prime mover does not increase at the same rate as its power: economies in the price of raw materials, recycling of waste, reduction in administrative costs, or in storage costs as the result of mass production, etc. – all these *relative* savings accruing to constant capital and coinciding with the absolute growth in its value are based on the fact that these means of production, i.e. both the means and the materials of labour, are used *collectively*. This *collective* use in its turn is based on the absolute premiss of the co-operation of an agglomeration of workers. It is itself, therefore, only the objective expression of the *social character of labour* and the social forces of production arising from it, just as the particular form assumed by these conditions, the machinery for instance, cannot possibly be used other than for work on a co-operative basis. To the worker who enters into these relations, however, they appear as *given* conditions, *independent* of himself; they are the *forms of capital*. In consequence, all these economies (and the resultant growth in profits and reductions in the price of goods) seem to be something quite separate from the *surplus labour* of the worker. They appear to be the direct *act* and *achievement of the capitalist*, who functions here as the personification of the *social* character of labour, of the *workshop as a whole*. In the same way, *science*, which is in fact the general intellectual product of the social process, also appears to be the direct offshoot of capital (since its application to the material process of production takes place in isolation from the knowledge and abilities of the individual worker). And since society is marked by the exploitation of labour by capital, its development appears to be the productive force of capital as opposed to labour. It therefore appears to be the *development of capital*, and all the more so since, for the great majority, it is a process with which the *drawing-off of labour-power* keeps pace.

The capitalist himself wields power only inasmuch as he is the personification of capital. (It is for this reason that he always appears in a dual role in Italian book-keeping. For instance, as the debtor of his own capital.)

As regards capital in the context of the *formal* mode of subsumption, its *productivity* consists in the first instance only in the *compulsion to perform surplus labour.* This compulsion is one which it shares with earlier modes of production, but in capitalism it is more favourable for production.

Even if we consider just the *formal* relation, the *general* form of capitalist production, which is common to both its more and its less advanced forms, we see that the *means of production,* the *material conditions of labour,* are not subject to the worker, but he to them. Capital *employs* labour. This in itself exhibits the relationship in its simple form and entails the personification of things and the reification [*Versachlichung*] of persons.

The relationship becomes more complicated, however, and apparently more mysterious, with the emergence of the specifically capitalist mode of production. Here we find that it is not only such things – the products of labour, both use-values and exchange-values – that rise up on their hind legs and face the worker and confront him as '*Capital*'. But even the social form of labour appears as a *form of development of capital,* and hence the productive forces of social labour so developed appear as the *productive forces of capitalism. Vis-à-vis* labour such social forces are in fact '*capitalized*'. In fact *collective* unity in co-operation, combination in the division of labour, the use of the forces of nature and the sciences, of the products of labour, as *machinery* – all these confront the individual workers as something *alien, objective, ready-made,* existing without their intervention, and frequently even hostile to them. They all appear quite simply as the prevailing forms of the instruments of labour. As objects they are independent of the workers whom they *dominate.* Though the workshop is to a degree the product of the workers' combination, its entire intelligence and will seem to be incorporated in the capitalist or his understrappers [Marx's word], and the workers find themselves confronted by the *functions* of the capital that lives in the capitalist. The social forms of their own labour – both subjectively and objectively – or, in other words, the forms of *their own* social labour, are utterly independent of the individual workers. Subsumed under capital the workers become components of these social formations, but these social formations do not belong to them and so rise up against them as the *forms* of capital itself, as if they belonged to capital, as if they arose from it and were integrated within it, in opposition to the isolated labour-power of the workers. And this entire process is progressively intensified as their labour-power is itself modified by these forms to such an extent that it is rendered impotent even when it exists autonomously. In other words its independent productive capacities are destroyed once it finds itself outside the framework of capitalism. And on the other hand, with the development of machinery there is a sense in which the conditions of labour come to dominate labour even technologically and, at the same time, they replace it, suppress it and render it superfluous in its independent forms. In this process, then, the *social* characteristics of their labour come to confront the workers so to speak in a *capitalized* form; thus machinery is an instance of the way in which the visible products of labour take on the appearance of its masters. The same transformation may be observed in the forces of nature and science, the products of the general development of history in its abstract quintessence. They too confront the workers as the *powers* of capital. They become separated effectively from the skill and the knowledge of the individual worker; and even though ultimately they are themselves the products of labour, they appear as an *integral* part of capital wherever they intervene in the labour process. The capitalist who puts a machine to work does not need to understand it. (See Ure.) But the science realized *in the machine* becomes manifest to the workers in the form of *capital*. And in fact every such application of *social labour* to science, the forces of nature and the products of labour on a large scale, appears as no more than the *means for the exploitation of labour*, as the means of appropriating surplus labour, and hence it seems to deploy *forces* distinct from labour and integral to capital. Of course, capital makes use of these means only in order to exploit labour, but if it is to exploit it, it must apply them to production itself. And so the development of the *social* productive forces of labour and the conditions of that development come to appear as the *achievement of capital*, an achievement which the individual worker endures passively, and which progresses at his expense.

Since capital consists of commodities, it appears in twofold form:

(1) *Exchange-value* (money), but value *valorizing* itself, value

that creates value, *grows as value*, receives an increment simply because it is *value*. This resolves itself into the exchange of a given quantity of objectified labour for a larger amount of living labour.

(2) *Use-value*, and here capital conforms to the specific nature of the labour process. And precisely here it is not limited to the materials or means of labour to which *labour* belongs, which have absorbed labour. But along with labour it has also appropriated its network of *social relations* and the level of development of the means of labour corresponding to them. Capitalist production is the first to develop the conditions of the labour process, both its objective and subjective ones, on a large scale – it tears them from the hands of the individual independent worker, but develops them as powers that control the individual *worker* and are *alien* to him.

In this way capital becomes a highly mysterious thing.

491 The conditions of labour pile up in front of the worker as *social forces*, and they assume a *capitalized* form.

Thus capital appears *productive*:

(1) as the *compulsion to surplus labour*. Now if labour is *productive* it is precisely as the agent that performs this surplus labour, as the result of the difference between the actual value of labour-power and its valorization.

(2) as the *personification and representative*, the reified form of the 'social productive forces of labour' or the productive forces of social labour. How the law of capitalist production – the creation of surplus-value, etc. – achieves this has already been discussed. It takes the form of a compulsion which the capitalists impose upon the workers and on each other: – in reality, then, it is the law of capital as enforced against both. Labour as a social and natural force does not develop within the valorization process as such, but within the *actual labour process*. It presents itself therefore as a set of attributes that are intrinsic to capital as a thing, as its use-value. Productive labour – as something productive of value – continues to confront capital as the labour of the *individual* workers, irrespective of the social combinations these workers may enter into in the process of production. Therefore whereas capital always represents the social productivity of labour *vis-à-vis* the workers, productive labour itself never represents more than the labour of the *individual* worker *vis-à-vis* capital.

We have already seen in our discussion of the *process of accumulation* how past labour, i.e. labour in the form of the forces and conditions of production already produced, intensifies reproduction both as use-value and exchange-value; i.e. both in terms of the mass of value which a specific quantum of living labour *sustains*, as also the *mass of use-values* it creates anew. And we have seen how this manifests itself as a *force immanent in capital*, because the *objectified labour* always functions as capitalized labour *vis-à-vis* the worker.

'*Le capital c'est la puissance démocratique philanthropique et égalitaire par excellence*' [' Capital is the democratic, philanthropic and egalitarian power par excellence'] (F. Bastiat, *Gratuité du crédit, etc.*, Paris, 1850, p. 29).

'Stock cultivates land: stock employs labour' (Adam Smith, op. cit., Bk V, Ch. 2, ed. Buchanan, 1814, Vol. 3, p. 309).

'Capital is ... collective force' (John Wade, *History of the Middle and Working Classes etc.*, 3rd edn, London, 1835, p. 162). 'Capital is only another name for civilization' (ibid., p. 104).

'*La classe des capitalistes, considérée en bloc, se trouve dans une position normale, en ce que son bien-être suit la marche du progrès social*' (Cherbuliez, *Riche ou pauvre*, p. 75). '*Le capitaliste est l'homme social par excellence, il représente la civilisation*' (ibid., p. 76). ['The class of capitalists, considered as a whole, finds itself in a normal situation when its well-being keeps pace with the march of social progress ... The capitalist is social man par excellence: he represents civilization.]

Superficial: 'The *productive power of capital* is nothing but the quantity of real productive power which the capitalist can command by virtue of his capital' (John Stuart Mill, *Essays on Some Unsettled Questions of Political Economy*, London, 1844, p. 91).

'The accumulation of capital, or of the means of employing labour ... must in all cases depend on the *productive powers of labour*' (Ricardo, *Principles*, 3rd edn, 1821, p. 92). A commentator on Ricardo made the following observation on this point: '*If the productive powers of labour mean the smallness of that aliquot part of any produce that goes to those whose manual labour produced it*, the sentence is nearly identical' (*Observations on Certain Verbal Disputes in Political Economy*, London, 1821, p. 74).

The constant transposition of labour into capital is well formulated in the following naïve statements of *Destutt de Tracy*:

'*Ceux qui vivent de profits (les capitaux industrieux) alimentent tous les autres, et seuls augmentent la fortune publique et créent tous nos moyens de jouissance. Cela doit être*, puisque le travail est la source de toute richesse, *et puisque eux seuls donnent une* direction utile au travail actuel, *en faisant un usage utile du travail accumulé*' ['They' (the industrial capitalists) 'who live on profits maintain all the others and alone augment the public fortune and create all our means of enjoyment. That must be so, *because labour is the source of all wealth* and because they alone give a *useful direction to current labour*, by making a useful application *of accumulated labour*'] (Destutt de Tracy, *Traité d'économie politique*, p. 242). Because labour is the source of all wealth, capital is the augmenter of all wealth. '*Nos facultés sont notre seule richesse originaire, notre travail produit tous les autres, et tout travail bien dirigé est productif*' ['Our faculties are our only original wealth; our labour produces all other wealth, and all labour, properly directed, is productive'] (ibid., p. 243). Our capacities are our only original wealth. Hence the capacity for labour is no wealth. Labour produces all other forms of wealth; that is to say, it produces wealth for all others but itself, and it is not even wealth itself, but merely the product of wealth. All well-directed labour is productive; in other words, all productive labour, all labour that yields profit for the capitalist, is well directed.

The transposition of the social productivity of labour into the material attributes of capital is so firmly entrenched in people's minds that the advantages of machinery, the use of science, invention, etc. are *necessarily* conceived in this *alienated* form, so that all these things are deemed to be the *attributes of capital*. The basis for this is (1) the form in which objects appear in the framework of capitalist production and hence in the minds of those caught up in that mode of production; (2) the historical fact that this development first occurs in capitalism, in contrast to earlier modes of production, and so its *contradictory character appears* to be an integral part of it.

TRANSITION FROM SECTIONS II AND III TO SECTION I*

We have seen that capitalist production is the production of surplus-value, and as such (in the process of *accumulation*), it is at the same time the *production of capital* and the *production* and reproduction of the entire capitalist relation on a steadily increasing (expanding) scale. But the surplus-value is produced only as a part of the value of commodities and it appears in a specific quantum of commodities or surplus produce. Capital produces only *surplus-value* and reproduces itself only in its capacity as the *producer of commodities*. It is therefore with the *commodity* as its *immediate product* that we must concern ourselves once more. However, as we have seen, *commodities* are *incomplete results* regarded *formally* (i.e. as economic forms). Before they can function again as wealth (whether as money or as use-values), they must undergo certain formal changes and they must re-enter the process of exchange in order to do so. We must therefore take a closer look at the *commodity* as the first result of the capitalist process of production and then consider the further processes that it has to undergo. (Commodities are the elements of capitalist production, and commodities are its *product*; they are the form in which capital re-appears at the end of the process of production.)

---

* Marx actually gave this section the heading 'Transition from Sections I and II of This Chapter to Section III, Originally Treated as Section I',

We begin with the commodity, with this specific social form of the product – for it is the foundation and premiss of capitalist production. We take the individual product in our hand and analyse the formal determinants that it contains as a commodity and which stamp it as a commodity. Prior to capitalist production a large part of what was produced did not take the form of commodities, nor was it produced for that purpose. What is more, a large proportion of the products that went into production were not commodities and did not go into the process of production as commodities. The transformation of produce into commodities occurred only at isolated points; it affected only the surplus produce, or only particular sectors (such as manufactured goods). Produce as a whole did not enter into the process as merchandise, nor did it emerge as such from the process.[30] Nevertheless, within certain limits both goods and money were circulated and hence there was a certain evolution of trade: this was the *premiss and point of departure for the formation of capital* and the capitalist

[30] See the French work of around 1752 where it is alleged that before ... only wheat was regarded as merchandise in France.

---

following his intention to re-arrange the order of sections as explained on p. 949. To avoid confusion we have retitled it to conform with the order in which the three sections are presented here.

mode of production. We regard the commodity as just such a premiss and we proceed from the commodity as capitalist production in its simplest form. On the other hand, however, the *commodity* is a product, a result of capitalist production. What began as one of its components turns out later to be its own product. Only on the basis of capitalist production will the commodity become the general form of the product. And the more it evolves the more will all the ingredients of production become absorbed into the process.*

III: CAPITALIST PRODUCTION IS THE PRODUCTION AND REPRODUCTION OF THE SPECIFICALLY CAPITALIST RELATIONS OF PRODUCTION

The product of capitalist production is not only *surplus-value*; it is also *capital.*

Capital is, as we have seen, M–C–M, i.e. *value valorizing itself*, value that gives birth to value.

In the first instance, even after its conversion into the factors of the labour process (i.e. into the means of production, *constant* capital on the one hand – and *labour-power* into which the variable capital has been transformed, on the other), the value or money invested is only capital *in itself*, only *potentially*. And this was even truer before it was transposed into the factors of the actual process of production. Only when it finds itself within that process, only when living labour is *really* incorporated into the objectively existent forms of capital, only when additional labour is sucked into the process, only then do we find that *this labour* is converted into capital. And furthermore, we then find that the amounts of potential capital, of what has been capital in intention, what has actually been invested, have also been transformed into capital in actuality and in effect. What took place in this process as a whole? The worker sold the right to control his labour-power in exchange for the necessary means of subsistence. He did so for a specific value which was determined by the value of his labour-power. Looking at him, what is the result? *Simplement et purement* the reproduction of his labour-power. So what did he part with? The activity that maintains value, that creates and augments it: his labour. Thus, if we ignore the exhaustion of his labour-power, he emerges from the process as he entered it, namely as a merely subjective labour-power which must submit itself to the same process once more if it is to survive.

---

*After the heading to the two foregoing paragraphs Marx made the note: 'Cf. p. 444'. It is for this reason that we have inserted the text of this last paragraph here. In the MS. it is emphasized by a number of brackets.

In contrast to this, capital does not emerge from the process as it entered it. It only becomes real capital, value valorizing itself, *in the course* of the process. It now exists as capital realized in the form of the aggregate product, and as such, as the property of the capitalist, it now confronts labour once more as an autonomous power even though it was created by that very labour. Hence the process does not reproduce just capital, but also the product. Previously, the conditions of production confronted the worker as capital only in the sense that he *found* them existing as *autonomous* beings opposed to himself. What he now finds so opposed to him is the product of his own labour. What had been the premiss is now the result of the process of production.

To say that the process of production creates *capital* is, to that extent, just another way of saying that it has created *surplus-value.*

But the matter does not rest there. The surplus-value is changed back into additional capital; it manifests itself as the formation of new capital or of enlarged capital. Hence *capital* has created *capital*; it has not just realized itself as capital. The *process of accumulation* is itself an intrinsic feature of the capitalist process of production. It entails the *new creation of wage-labourers*, of the means to realize and increase the available amount of capital. It does this either by extending its rule to sections of the population not previously subject to itself, such as women or children; or else it subjugates a section of the labouring masses that has accrued through the natural growth of the population. On closer inspection it becomes evident that capital itself *regulates* this production of labour-power, the production of the mass of men it intends to exploit in accordance with its own needs. Hence capital not only produces capital, it produces a growing mass of men, the material through which alone it can function as additional capital. Therefore, it is not only true to say that labour produces on a constantly increasing scale the conditions of labour in opposition to itself in the *form* of *capital*, but equally, capital produces on a steadily increasing scale the productive wage-labourers it requires. Labour produces the conditions of its production in the form of *capital*, and capital produces labour, i.e. as wage-labour, as the means towards its own realization as *capital*. Capitalist production is not merely the reproduction of the relationship: it is its reproduction on a steadily increasing scale. And just as the social productive forces of labour develop in step with the capitalist mode of production, so too the heaped-up wealth confronting the worker grows apace and confronts him as *capital*, as *wealth that controls him*. The world of wealth expands and faces him as an alien world dominating him, and as it does so his subjective poverty, his need and dependence grow larger in proportion. His *deprivation* and its *plenitude* match each other exactly. And at the same time, there is a corresponding increase in the mass of this living means of production of capital: the labouring proletariat.

493 The *growth of capital* and the *increase in the proletariat* appear, therefore, as interconnected – if opposed – *products* of the same process.

This relation is not merely reproduced, it is produced on a steadily more massive scale, so that it creates ever new supplies of workers and encroaches on branches of production previously independent. In addition, as we have seen in our account of the mode of production specific to capitalism, the relation is reproduced in a fashion increasingly favourable to the one side, the capitalists, and increasingly unfavourable to the other side, the wage-labourers.

If we consider the continuity of the process of production, the labourer's wage is only that *part* of the product constantly produced by the worker, who converts it into the means of subsistence and hence into the means for the preservation and increase of the labour-power which capital requires to valorize value for itself, i.e. for its own life-process. The maintenance and increase of labour-power appear therefore merely as the reproduction and extension of its own conditions of reproduction and accumulation. (See the Yankee.)*

This destroys the last vestiges of the *illusion*, so typical of the relationship when considered superficially, that in the circulation process, in the market-place, two equally matched *commodity owners* confront each other, and that they, like all other *commodity owners*, are distinguishable only by the material content of their

---

*H. C. Carey, in *Principles of Political Economy*, Part I, pp. 76–8.

goods, by the specific use-value of the goods they desire to sell each other. Or in other words, the *original* relation remains intact, but survives only as the *illusory* reflection of the *capitalist* relation underlying it.

There are two distinct features here: the *reproduction of the relation itself* on a steadily increasing scale as the result of the capitalist process of production, and the original form in which it first appears *historically*, and then constantly renews itself on the surface of a developed capitalist society.

(1) *First, with regard to the initial process* within the sphere of circulation, *the sale and purchase of labour-power.*

The capitalist process of production is not just the *conversion* into *capital* of the value or of the commodity which the capitalist partly puts on the market and partly retains within the labour process. On the contrary, these products *transformed* into capital are not *his* products, but the products of the worker. He constantly sells him a portion of his product – the necessities of life for his labour – in order to maintain and increase the labour-power, i.e. the purchaser himself. And he borrows from him in return another portion of his product, the objective conditions of labour, as *capital*, as the means whereby capital can valorize itself. Thus, while the worker produces his produce as *capital*, the capitalist reproduces the worker as a *wage-labourer* and hence as the vendor of his labour. The relation of people who merely sell commodities is that they exchange *their own labour* objectified in different use-values. However, the sale and purchase of labour-power, as the constant result of the capitalist process of production, implies that the worker must constantly *buy back* a portion of his own produce in exchange for his living labour. This *dispels* the illusion that we are concerned here merely with *relations between commodity owners.* This constant sale and purchase of labour-power, and the constant entrance of the commodity produced by the worker himself as *buyer of* his labour-power and as constant capital, appear merely as *forms which mediate* his subjugation by capital. Living labour is no more than the means of maintaining and increasing the *objective* labour and making it independent of him. This form of mediation is intrinsic to this mode of production. It perpetuates the relation between capital as the buyer and the worker as the seller of labour. It is a form, however, which can be distinguished only formally from other more direct forms of the enslavement of labour and the *ownership of it* as perpetrated by the

owners of the means of production. Through the mediation of this sale and purchase it *disguises* the real transaction, and the perpetual dependence which is constantly renewed, by presenting it as nothing more than a financial relationship. Not only are the conditions of this *commerce* constantly reproduced, but the object which the one must sell and which the other uses in order to buy
494 are themselves the result of the process. The constant renewal of the relationship of *sale and purchase* merely ensures the perpetuation of the specific relationship of dependency, endowing it with the deceptive *illusion* of a transaction, of a contract between equally free and equally matched *commodity owners*. This *initial* relationship itself now appears as an integral feature of the rule of objectified labour over living labour that is created in capitalist production.

It follows that two widely held views are in error:

There are firstly those who consider that wage-labour, the sale of labour to the capitalist and hence the *wage form*, is something only *superficially* characteristic of capitalist production. It is, however, one of the *essential* mediating forms of capitalist relations of production, and one constantly reproduced by those relations themselves.

Secondly, there are those who regard this superficial relation, this *essential formality*, this *deceptive appearance* of capitalist relations as its true *essence*. They therefore imagine that they can give a true account of those relations by classifying both workers and capitalists as *commodity owners*. They thereby gloss over the essential nature of the relationship, extinguishing its *differentia specifica*.

(2) For capitalist relations to establish themselves at all presupposes that a certain historical level of social production has been attained. Even within the framework of an earlier mode of production certain needs and certain means of communication and production must have developed which go beyond the old relations of production and coerce them into the capitalist mould. But for the time being they need to be developed only to the point that permits the formal subsumption of labour under capital. On the basis of that change, however, specific changes in the mode of production are introduced which create new forces of production, and these in turn influence the mode of production so that new real

conditions come into being. Thus a complete economic revolution is brought about. On the one hand, it creates the real conditions for the domination of labour by capital, perfecting the process and providing it with the appropriate framework. On the other hand, by evolving conditions of production and communication and productive forces of labour antagonistic to the workers involved in them, this revolution creates the real premisses of a new mode of production, one that abolishes the contradictory form of capitalism. It thereby creates the material basis of a newly shaped social process and hence of a new social formation.

The view outlined here diverges sharply from the one current among bourgeois economists imprisoned within capitalist ways of thought. Such thinkers do indeed realize how production takes place *within* capitalist relations. But they do not understand how these *relations* are themselves produced, together with the material preconditions of their dissolution. They do not see, therefore, that their *historical justification* as a *necessary form* of economic development and of the production of social wealth may be undermined. Unlike them, we have seen both how capital produces, and how it is itself produced, and we have seen also how it emerges from the process of production as something essentially different from the way it entered into it. On the one hand, it transforms the existing mode of production; on the other hand, this change in the mode of production, the particular stage reached in the evolution of the material forces of production, is itself the basis and precondition – the premiss of its own formation.

495 RESULTS OF THE IMMEDIATE PROCESS OF PRODUCTION

It is not just the objective conditions of the process of production that appear as its result. The same thing is true also of its *specific social* character. The social relations and therefore the social position of the agents of production in relation to each other, i.e. the *relations of production*, are themselves produced: they are also the constantly renewed result of the process.*

---

*The text of the manuscript breaks off at this point. What follows now are isolated fragments which were evidently meant to be revised and incorporated in the present version. We print them in the arbitrary order that results from following Marx's own pagination, which contains lacunae of considerable magnitude. Titles in square brackets have been added by the present editor.

IV: [ISOLATED FRAGMENTS]

[THE SALE OF LABOUR-POWER AND THE TRADE UNIONS]

24 [temporary control over] his labour-power. By the time his labour actually begins it has already ceased to belong to the worker and as a result can no longer be *sold* by him.

In consequence of the peculiar nature of this particular commodity, namely labour-power, the commodity sold only passes into the hands of the purchaser* as a use-value after the conclusion of the contract between buyer and seller. Its exchange-value, like that of every other commodity, is determined before it goes into circulation, since it is sold as a capacity, a power, and a specific amount of labour-time was required to produce this capacity, this power. The exchange-value of this commodity existed, therefore, before its sale, while its use-value consists only in the subsequent expression of its power. That is to say, the alienation of the power and its actual expression, i.e. its existence as a use-value, do not coincide in time. It is the same as with a house whose use has been sold to me for a month. In such a case the use-value has been transferred to me only when I have lived there for a month. In the same way, the use-value of labour-power is transferred to me only after I have used it up, i.e. after I have caused it to work for me. However, where the formal alienation of the commodity through sale does not coincide in time with the real transfer of its use-value to the purchaser, the buyer's money functions as we have seen in the first instance as a *means of payment*. The labour-power is *sold* for a day, a week, etc., but it is *paid for* only after it has been consumed for a day or a week, etc. In all countries where capitalist relations are in the process of development, labour-power is only *paid for* after it has been used up. As a rule, then, the worker *advances* the use of his commodity to the capitalist. He permits its consumption by the buyer, he allows him *credit*, before he receives its exchange-value in payment. At times of crisis and even in the event of individual bankruptcies we can see that, because of the special nature of the use-value sold, the idea that the worker constantly gives credit to the capitalist is no empty delusion.[31]†

[31] *'L'ouvrier* prête *son industrie'* ['The worker *lends* his industry'] (Storch, *Cours d'économie politique*, St Petersburg edition, 1815, Vol. 2, p. 36).

*The MS. had 'vendor'.

†The above paragraph was included in *Capital*, along with n. 31. See above, p. 278.

However, whether money is used as a means of purchase or a means of payment is immaterial to the nature of commodity exchange itself. The price of labour-power is fixed contractually in the purchase even though it is only realized later. Nor does this form of payment influence the fact that the price pertains to the *value of the labour-power* and is unrelated either to the *value of the product* or to the *value of the labour* which as such is not a commodity at all.

As has been shown, the *exchange-value* of labour-power is paid for when the price paid is that of the means of subsistence that is customarily held to be essential in a given state of society to enable the worker to exert his labour-power with the necessary degree of strength, health, vitality, etc. and to perpetuate himself by producing replacements for himself.[32]

However, Storch adds slyly 'he *risks nothing*' but 'perdre son salaire ... *l'ouvrier ne transmet* rien de matériel' ['*to lose his wages* ... the working man transmits *nothing material*'] (ibid., p. 37). 'All labour is paid after it has ceased' (*An Inquiry into Those Principles, Respecting the Nature of Demand, etc.*, London, 1821, p. 104). Other practical consequences arising from this mode of payment, which is incidentally founded in the nature of the relationship, cannot detain us here. However, one example may be in place. In London there are two sorts of bakers, the 'full-priced' who sell bread at its *full price* and the *undersellers* who sell it at *less*. The latter comprise more than ¾ of all bakers (report of the Government Commissioner, H. S. Tremenheere, on the *Grievances Complained of by the Journeymen Bakers, etc.*, London, 1862, p. xxxii). These 'undersellers' mostly sell bread adulterated with alum, soap, pearl-ashes, chalk, Derbyshire stone-dust, etc. (Vide the above-mentioned Blue Book, and also the *Report of the Committee of 1855 on the Adulteration of Bread* and C. Hassall's *Adulterations Detected*, 2nd edn, London, 1861.) Sir John Gordon stated before the Committee of 1855 that because of these adulterations 'the poor men who lived on 2 lb. of bread a day did not take in one-fourth of that amount of nutrition', to say nothing of the 'deleterious effects on health'. Tremenheere explains (ibid., p. xlviii) why 'a very large part of the working class' accepted the alum, stone-dust, etc., although they were aware of the adulteration: he points out that for them it was 'a matter of necessity to take from their baker, or from the chandler's shop such bread as they choose to supply'. Since they receive their wages only at the end of the week they can 'only pay for the week's supply to the family at the week's end'. And Tremenheere adds, citing the testimony of eye-witnesses, that 'it is notorious that *bread composed of those mixtures, is made expressly for sale in this manner*'.

[32] *Petty* defines the value of the daily working wage as the value of the 'daily food' sufficient for the worker 'so as to live, labour and generate' (*Political Anatomy of Ireland*, London, 1672, edn of 1691, p. 64. Quoted

Man is distinguished from all other animals by the limitless and flexible nature of his needs. But it is equally true that no animal is able to restrict his needs to the same unbelievable degree and to reduce the conditions of his life to the absolute minimum. In a word, there is no animal with the same talent for 'Irishing' himself. Such a reduction to the bare *physical minimum* is not at issue when we are discussing the *value* of labour-power. As with every commodity so it is true of labour-power that its price can rise *above* its value or fall *beneath* it, i.e. its value can deviate in either direction from the price, which is only the monetary expression of its value. The level of the necessaries of life whose total value

---

from Dureau de la Malle). 'The price of labour is always constituted of the price of necessaries.' The worker does not receive the corresponding wage 'whenever the price of necessaries is such, that the labouring man's wages will not, *suitably* to his low rank and station, as a labouring man, support *such a family* as is often the lot of many of them to have' (Jacob Vanderlint, *Money Answers All Things*, London, 1734, p. 15).

'Le simple ouvrier, qui n'a que ses bras et son industrie, n'a rien *qu'autant qu'il parvient à vendre à d'autres sa peine ... En tout genre de travail* il doit arriver et il arrive en effet, *que le salaire de l'ouvrier se borne à ce qui lui est nécessaire pour lui procurer sa subsistance'* ['This simple worker, with only his limbs and his industry, has *only* what he manages to sell his labour for. For every kind of labour *it must result, and it does in fact result*, that what he receives is limited to the sum necessary for his means of subsistence.'] (Turgot, *Réflexions sur la formation et la distribution des Richesses* (1766), *Œuvres*, Vol. 1, p. 10, ed. Daire, Paris, 1844).

'The price of the necessaries of life is, in fact, the cost of producing labour' (Malthus, *Inquiry into, etc. Rent*, London, 1815, p. 48, note). 'Another inference we may draw from a review comparing the price of corn and the wages of labour since the reign of Edward III, is that during the course of nearly 500 years, the earnings of a day's labour in this country have probably been more frequently below than above a peck of wheat (= ¼ bushel); that a peck of wheat may be considered as something like a middle point, or a point rather above the middle, about which the corn wages of labour, varying according to the demand and supply, have oscillated' (Malthus, *Principles of Political Economy*, 2nd edn, London, 1836, p. 254).

'The natural price of any article is that ... bestowed upon its production ... Its' (labour's) 'natural price ... consists of such a quantity of the necessaries and comforts of life, as, from the nature of the climate and the habits of the country, are necessary to support the labourer, and to enable him to rear such a family as may preserve, *in the market*, an undiminished supply of labour ... The natural price of labour ... though it varies under different climates, and with the different stages of national improvement, may, in any given time and place, be regarded as very nearly stationary' (R. Torrens, *An Essay on the External Corn Trade*, London, 1815, pp. 55–65 passim).

constitutes the value of labour-power can itself rise or fall. The analysis of these variations, however, belongs not here but in the theory of wages.[33] It will become apparent in the course of these discussions that for the analysis of capital it is a matter of complete indifference whether the level of the worker's needs is assumed to be high or low. In practice, as in theory, the point of departure is the *value* of labour-power regarded as a *given quantity*. Thus, for example, the owner of money who desires to convert his money into capital, let us say into the industrial capital of a cotton factory, will inquire above all into the average wages paid in the locality where he intends to set up his factory. He knows full well that wages, like cotton, continually diverge from that average, but he knows too that these variations cancel each other out. For this reason wages enter his calculations as a *given value*. On the other hand, the *value of labour-power* constitutes the conscious and explicit foundation of the *trade unions*, whose importance for the English working class can scarcely be overestimated. The *trade unions* aim at nothing less than to prevent the *reduction of wages* below the level that is traditionally maintained in the various branches of industry. That is to say, they wish to prevent the *price* of labour-power from falling below its *value*. They are aware, of course, that if there is a change in the relations of supply and demand, this results in a change in the market price. But on the one hand this change is a very different thing from the one-sided claim of the buyer, in this case the capitalists, that such a change has taken place. And on the other hand, there is 'a great distinction between the level of wages as determined by supply and demand, i.e. by the level produced by the fair operation of exchange that exists when buyer and seller *negotiate on equal terms*, and the level of wages which the seller, the labourer, must put up with when the capitalist negotiates with each man *singly*, and dictates a reduction by exploiting the chance need of individual workers (which exists independently of the general relations of supply and demand). The workers *combine* in order to achieve *equality* of a sort with the capitalist in their *contract concerning the sale of their labour*. This is the *rationale* (the logical basis) of the *trade unions*.'[34] What they purpose is that 'the accidental immediate neediness of a labourer should not compel him to make do with a smaller wage than supply and demand has *already* established in a particular branch of labour'[35] and thus depress the *value* of labour-power in a particular area below its customary level. The *value* of labour-power is 'regarded by the workers themselves as the *minimum wage* and by the capitalist as the *uniform rate of wages* for all workers in the same trade'.[36] For this reason the unions never allow their members to work for *less* than this minimum.[37] They are insurance societies formed by the workers themselves. An example may explain the purpose of these combinations formed by the workers for the protection of the *value* of their labour-power. In all branches of trade in London there are so-called 'sweaters'. A *sweater* is someone who undertakes to deliver a certain quantity of work at normal prices to an entrepreneur, but who then has it carried out for a lower price by others. The difference, which goes to make up his profit, is *sweated out* of the workers who actually perform the labour[38] and represents nothing but the difference between the *value* of the labour-power that is *paid* by the first entrepreneur and the price which is equivalent to *less than* the value of that labour-power and which is paid by the *sweater* to the actual workers.[39]

---

[33] 'When corn forms a part of the subsistence of the labourer, an increase in its natural price necessarily occasions an increase in the natural price of labour; or, in other words, when it requires a greater quantity of labour to procure subsistence, a greater quantity of labour, or of its produce, must remain with the labourer, as his wages. But, as a greater quantity of his labour, or (what is the same thing) of the produce of his labour, becomes necessary to the subsistence of the labouring manufacturer, and is consumed by him while at work, a smaller quantity of the productions of labour will remain with the employer' (R. Torrens, *An Essay on the External Corn Trade*, 1815, pp. 325, 236). [Marx marked this passage as a footnote to a now lost p. 244; we have inserted it here, where it seems apposite.]

---

[34] T. J. Dunning (Secretary to the London Consolidated Society of Bookbinders), *Trades' Unions and Strikes: Their Philosophy and Intention*, London, 1860, pp. 6, 7.

[35] ibid., p. 7.

[36] ibid., p. 17.

[37] It is obvious that the capitalists will denounce this *'uniform rate of labour'* as an attack on the personal freedom of the worker, as an obstacle which prevents the capitalists from following the promptings of their hearts and rewarding a special talent with a special wage. Mr Dunning, whose book, just cited, not only hits the nail on the head but also treats the subject with an apt turn of irony, retorts that the trade unions are happy to permit the capitalist 'to pay for superior skill, or working ability, as much more as he pleases', but would prevent him from depressing 99/100 of the mass of wages, i.e. the wages of 'the common run of men', the average worker in each trade, beneath the *'minimum wage'*. That is to say, they would prevent him from reducing the normal value of average labour-power. It is of course quite in order when the combinations of workers against the despotism of capital are denounced by an Edinburgh Reviewer (Concerning the Combinations of Trade, 1860)* as a slavery which these free-born Englishmen submit to in consequence of incomprehensible delusion. In war it is always desirable for an enemy to refuse to subject itself to the despotism of discipline. The morally indignant Reviewer uncovers even more odious facts. The trade unions are a *sacrilege* for they offend against the laws of *free trade*! *Quelle horreur*! Mr Dunning replies *inter alia*: 'It would not be a *free exchange* of blows if one of the parties were to have one arm disabled or tied down, while the other had the free use of both . . . the employer wishes to deal with his men singly, so that he, whenever he pleases, may give the "sweaters" price for their labour;

*This is in fact a reference to the article 'Secret Organization of Trades' which appeared in No. 224 of the *Edinburgh Review* (October 1859).

Incidentally, it is a highly characteristic* . . .

*

259 The form of *piece wages* is used for example in the English potteries to engage young apprentices (in their thirteenth year) at a low rate so that they overwork themselves 'for the great benefit of their masters' in the very period of their own development. This is given officially as one of the reasons for the degeneration of the population in the pottery factories.[40]

---

their right arm as bargainers being tied down by their necessities in its sale. This he calls *free trade*, but the freedom is all on his own side. Call it *trade*, if you will, it is not free *exchange*' (op. cit., p. 47).

[38] ibid., p. 6.

[39] 'A philanthropic association has been formed in London for the purpose of contracting to deliver military clothing at prices identical with those paid at present to contractors by the government, while paying the starving sempstresses an extra 30 per cent on top of their present wages. This result is achieved by eliminating the "middleman" whose profits will go to the human material from which he has hitherto carved them. With all the benefits that the association can afford, a sempstress cannot earn more than 1 shilling for 10 hours' uninterrupted work on military shirts, namely at a rate of two shirts per day, and in the case of other articles of clothing not more than 1s. 6d. a day, for a day of 12 hours' work. At the present time their wages vary from 5d. to 8d. for 10 hours' work, for which moreover they have to supply their own yarn, etc.' (*The Times*, 13 March 1860).

[40] 'There are, in the employ of the manufacturer, many youths who are taken as apprentices at the early ages of 13 and 14 as flat-ware pressers and hollow-ware pressers. For the first two years they are paid weekly wages of 2s. to 3s. 6d. per week. After that they begin to work on the *piece-work system*,

---

*At this point the MS. of p. 25 breaks off.

The raising of the overall wage (the weekly wage, for example) frequently occurs in branches of industry where piece-work has been freshly introduced. But as soon as it has reached a certain rate, this rise which has been brought about by the increased intensity of labour becomes itself a reason for the masters to reduce wages, since they regard them as higher than is good for the worker. Piece-work as a means for depressing wages is to be denounced directly.[41]

It must be made perfectly clear that the way *in which* wages are paid out does not affect the situation in the least, although one mode of payment may well favour the development of the capitalist process of production more than another and we may note in passing that the technical nature of the process may sometimes permit only one or the other mode.

It is clear that *individual* variations in wages, variations which have greater scope in wages by piece than in wages by time, are only deviations from the level of wages in general. However, wages by the piece if not prevented by other circumstances tend to depress the general level.*

Wages as the *aggregate price* of the average daily labour contradict the concept of value. Every price must be reducible to *value*, since the price is in itself nothing but the monetary expression of value and the fact that actual prices may stand above or below the price corresponding to their value does not alter the fact that they are a quantitatively incongruent expression of the value of the commodity – even if in the situation assumed they may be *quantitatively*

---

earning journeymen's wages. "The practice," as Longe says, "of employing a great number of apprentices and taking them at the age of 13 and 14 is very common in a certain class of manufactories, a practice which is not only very prejudicial to the interests of the trade, but is probably another great cause to which the *bad constitutions of the potters are to be attributed*. This system, *so advantageous to the employer*, who requires quantity rather than quality of goods, tends directly to encourage the young potter *greatly to overwork himself* during the four or five years during which he is employed on the piece-work system, but at low wages." The consequences of over-work in the hot stoves at that early age may readily be anticipated' (*Children's Employment Commission, First Report*, London, 1863, p. xiii).

[41] 'Indeed, the main objection in different trades to *working by the piece*, is the complaint that, when men are found to earn good wages at it, the *employer wishes to reduce the price* of the work, and that *it is so often made use of as a means of reducing wages*' (Dunning, op. cit., p. 22).

---

*This paragraph is crossed through once in the MS.

too great or too small. But here in the *price of labour* the lack of congruence is *qualitative.*

260 Since the value of a commodity equals the necessary labour it contains, then the value of a day's labour – a day's labour performed under adequate conditions of production and with the average *normal* social measure of intensity and skill – would be equal to the day's labour contained in it, which is nonsense and affords no definition. The *value of labour* – i.e. the price of labour (qualitatively) stripped of its monetary expression – is then an irrational expression and in fact is no more than a disguised and inverted form for the *value of labour-power.* (*Price* which is not reducible to *value,* whether immediately or through a series of mediations, expresses a merely accidental exchange of something for money. In this way articles which are not *commodities* in themselves, and which therefore are in this sense *extra commercium hominum,** may be converted into commodities by being exchanged for money. Hence the connection between venality and corruption and the money relationship. Since money is the transformed shape of the commodity it does not reveal what has been transformed into it: whether conscience or virginity or horse dung.)

But just as irrational as time-wages, the most immediate form of wages, are piece-wages, which are supposed to be the immediate expression of a value relationship. For example, suppose that one hour's labour, equal to 6d., let us say, is objectified in a piece of a given commodity (setting aside the constant capital it contains). The worker receives 3d., since otherwise the *value of this piece* is not determined *vis-à-vis* the worker by the *value* contained in it as measured by the labour-time consumed. In fact, therefore, this piece-wage does not express any value relationship *directly.* The point, therefore, is not to measure the value of the piece by the amount of labour-time contained in it. On the contrary, the necessary labour-time performed by the worker must be measured by the piece. *The wage the worker receives,* therefore, *is a time-wage,* since the piece only has the task of measuring the time for which he receives his wages and of acting as a guarantee that he uses only *necessary labour time,* i.e. that he has worked at the right intensity and that his labour (as a use-value) is of the appropriate quality. *Piece-wages,* then, are nothing but a *specific form* of time-wages, which in their turn are nothing but the disguised form of the

---

*'Outside human commerce'.

value of labour-power, alternatively of the *price of labour-power* corresponding quantitatively to or deviating from that value. If it is true that piece-wages tend to leave great scope for the individual worker to rise more or less above the general level, then it is no less true that they reduce the wages of other workers below that level and that the level itself tends to fall as a result of the extremely intense competition among the workers that piece-wages inspire.

In a comparison between the time-wages in different countries (i.e. the wage for a working day of given length), in so far as the intensity of labour is measured – other things being equal – by the mass of the product yielded by the worker in a given time, one must at the same time compare these wages in terms of piece rates. This is the only way to discover the true relation between necessary and surplus labour, or between wages and surplus-value. It will then often turn out that although the apparent time-wages are higher in rich countries, piece-wages are higher in poorer ones. Hence, in the latter, the worker requires a greater portion of the working day to reproduce his salary than in the former, i.e. the rate of surplus-value is smaller in the latter than the former and the relative wage is therefore greater. So in fact the real price of labour is higher in poor countries than in rich ones. Looking at various nations we find that, apart from the duration and the productivity independent of the individual worker, there is as great a variation in the intensity as in the duration of the working day. The more intensive national working day may be equated to the less intensive one $+x$. If we take the working day of the countries that produce gold and silver as the standard of the international working day, then the more intensive English working day of 12 hours can be expressed in more gold than the less intensive Spanish day. That is to say, it will stand higher in comparison to the medium working day as expressed in terms of gold and silver. A higher national working wage, assuming an aggregate day of fixed length, will stand higher then, both in terms of use-value and of exchange-value, and hence also in terms of its monetary expression. (Assuming a given value in gold and silver, a higher monetary expression must always express more value, and a lower, less: looking at the money-wages of workers in different countries *simultaneously*, the *value of gold and silver* is assumed to be constant as even a change in their value would mean a simultaneous change for all the nations concerned, so that as far as their relative positions are concerned *no* change occurs at all.) The fact of a higher national wage, then, does not imply a higher *price for labour* as the price of a certain amount of labour. Given the greater duration of work, or, what amounts to the same thing internationally, a greater intensity of labour, the wage can be higher in one country than another, but it may firstly occupy a smaller portion of the aggregate day, i.e. be smaller relatively speaking, and secondly it may represent a lower *price*. For example, if the worker receives 3s. daily for 12 hours' work, this is less than if his day's wages were 2½s. for 11 hours. For the one hour of surplus labour involves far more wear and tear, i.e. a speedier reproduction of labour-power. The difference would be even greater in the event of his receiving 2½s. for 10 and 3 for* . . .

[DIFFERENT MODES OF CENTRALIZATION OF THE MEANS OF PRODUCTION IN DIFFERENT COUNTRIES]

'Although skill and mechanical science may do much, the preponderance of the *vital element is essential in the extension of manufactures.* The system of *morcellement*,† in preventing a rapid development of the population, has thus tended indirectly to retard the extension of manufactures. It has also had that effect in a direct manner. It has retained a large population attached to and occupied upon the soil. The cultivation of the soil is their primary occupation – the one which they follow with pride and contentment. Their employment in spinning, weaving and the like is but a subsidiary one necessary for their support. Their savings are hoarded for the purpose of increasing their inheritance and they are not prone to wander from home in search of fresh occupation or new habits.' (So precisely here – where saving equals hoarding, and still exists to a relatively high degree and is able to exist under the given circumstances – the *formation of capital*, relatively speaking, and the *development of capitalistic* production are prevented in comparison to England, by the very same economical conditions that are favourable to hoarding, etc.) 'The position of a proprietor, the possession of a house, of a plot of ground, is the chief object also of the factory operative, and of almost every poor man who has not already a property; in fact, all look to the land... From this description of the character and occupations of a very numerous class of the French people, it will be readily inferred that unlike that of England, the manufacturing industry of France is represented by small establishments,' (this shows how necessary the expropriation of land is for the development of large-scale industry) 'some moved by steam and water, many dependent for their moving power upon animal labour and many factories still entirely employing manual labour only. The *characteristic of French industry* is well described by Baron C. Dupin, as *consequent upon the system of the tenure of land.* He says: "As France is the country of divided properties, that of small holdings, so it is the *country of the division of industry, and of small workshops*"' (*Reports of Inspectors of Factories . . . 31 October 1855*, pp. 67–8). The same factory inspector (A. Redgrave) provides a survey (for 1852) of French textile manufactures of whatever importance from which it appears that the source of power employed was as follows: *steam* 2,053 (h.p.), water 959 and other mechanical power 2,057 (ibid., p. 69).[42] He compares this return with the return of the number of factories, etc., presented to the House of Commons in 1850 and uses them to show 'the following remarkable difference between the system of textile manufacture of England and France'. The result is as follows:

---

*Pages 261 and 262 are missing. In their place is a sheet numbered 379, titled as shown, which in subject-matter follows on more or less naturally from the preceding text.

†'Parcellation'.

380 'The *number* of factories in France is *three times as large* as those in England, while the number of persons employed in them is only ⅕ greater; but the very different proportions of machinery and moving power will best be shown by the following comparison:

---

[42] What appears as the preliminary (primitive) accumulation of capital is in reality only the process by which the conditions of production become independent – they break loose from the self-employing producer who is transformed into a wage-labourer. In the text this is shown in the case of manufacturing. But it is also evident, for example, in the relations between the farming capitalist and the peasant etc. *'La grande culture n'exige pas une plus grande masse de capitaux que la petite ou la moyenne culture; elle en exige moins au contraire,* but in these different systems capital must be variously distributed; *dans la grande culture les capitaux appliqués à l'agriculture doivent se trouver entre les mains d'un petit nombre d'hommes qui salarient les bras qu'ils emploient'* ['Large-scale agriculture does not require a greater amount of capital than cultivation on a small or medium scale. On the contrary, it requires less . . . in large-scale agriculture the capital sums invested must be retained in the hands of a small number of men who pay the wages of the men they employ'] (Mathieu de Dombasle, *Annales agricoles de Roville*, 2-ème livraison, 1825, p. 218).

	France	England	
Number of factories	12,986	4,330	
Number of persons employed	706,450	596,082	In fact the figures for France include as factories what would not be counted as such in England
Average number of persons in each factory	54	137	
Average number of spindles to each person employed	7	43	i.e. six times as many in England as in France
Average number of persons to each loom	2 (power and handloom)	2	(powerloom only)

Hence there are in France *more* people employed than in England but only because all handloom weaving is excluded in the English return. But in the average establishment there are more than twice as many people than in France ($\frac{54}{136} = \frac{27}{68} = \frac{18}{34} =$ almost $\frac{1}{3}$), i.e. there is a much larger number of people brought together under the command of the same capital. In France there are three times as many factories, but only $\frac{1}{5}$ more people employed in them, i.e. *fewer* persons in proportion to the *number of establishments*. Furthermore, with regard to the mass of machinery falling to each person, there are six times as many spindles in England as in France. If all the persons employed were spinners there would be 4,945,150 spindles in France and in England $\frac{1}{5}$ fewer. So in England there is one power loom between two people, in France one power or one handloom. Thus in England there are 25,631,526 spindles. Furthermore, the steam power employed in factories of Great Britain = 108,113 h.p., the proportion of persons employed about 5½ persons to each horse-power of steam; the proportions in France upon this estimate should give a steam power = 128,409 h.p. whereas the *whole* of the steam power of France was only = 75,518 h.p. in 1852, produced by 6,080 steam-engines, of an average power of less than 12½ h.p. each; while the number of steam-engines employed in the text le

Persons	596,082
	43
	1 788 246
	2 384 328
	25,631,526

factories of France appears to have been 2,053 in 1852 and the power of those engines to be equal to 20,282 h.p., distributed as follows:

		Factories	Horse-power
Employed in	spinning only	1,438	16,494
„ „	weaving only	101	1,738
„ „	finishing etc.	242	612
„ „	other processes	272	1,438
		2,053	20,282

(ibid., p. 70).

'The absence in France of the bones and sinews of manufactures, coal and iron, must ever retard her progress as a manufacturing country' (ibid.).

For each worker in an English factory, compared to the Frenchmen, there is far more machinery for working and also far more power-driving machinery (mechanic power), and hence, too, far more raw materials are processed by him in the *same* time. The productive power of his labour is, therefore, much greater, as is the capital that employs him. The number of establishments is much smaller in England than in France. The number of working men employed on the average, in one single establishment, is much greater in England than in France, although the total number employed in France is greater than England, although in a small proportion only, compared to the number of establishments.

It becomes quite plain to see here that because of historical and other circumstances which have had a varying effect upon the *relative magnitude of the concentration of the means of production,* there is a correspondingly greater or smaller *expropriation* of the mass of immediate producers. In the same way, there is a very different development of the forces of production and of the *capitalist mode of production* in general. And this stands in inverse ratio to the 'saving' and 'hoarding' of the immediate producer himself, which in France is huge in comparison with England. The scale on which the surplus labour of the producers can be 'saved' and 'hoarded' and 'accumulated' and brought together in greater masses, i.e. *concentrated,* can be used as capital, corresponds exactly to the degree in which their surplus labour is hoarded, etc., by their employers instead of by themselves; it corresponds, therefore, to the degree in which the great mass of the real producers is precluded from the capacity and the conditions of 'saving', 'hoarding', 'accumulating', is, in one word, precluded from all power of appropriating its own surplus labour to any important degree, because of its more or less complete *expropriation* from its *means of production.* Capitalist accumulation and concentration are based upon, and correspond to, the facility of *appropriating other people's surplus labour in great masses* and the corresponding inability of these people themselves to lay any claim to their own surplus labour. It is, therefore, the most ludicrous delusion, fallacy or imposture to explain and account for this capitalist accumulation by confounding it with, and, as far as the phraseology is concerned, converting it into, a process quite its opposite, exclusive of it, and corresponding to a mode of production upon whose ruins alone capitalist production can be reared. This is one of the delusions carefully nurtured by Political Economy. The truth is this, that in this bourgeois society every workman, if he is an exceedingly clever and shrewd fellow, and gifted with bourgeois instincts and favoured by an exceptional fortune, can possibly be converted himself into an *exploiteur du travail d'autrui.** But where there was no *travail* to be *exploité*, there would be no capitalist nor capitalist production.

*

75.† In fact Ricardo consoles the workers by saying that, as a result of the mounting productivity of labour, the increase in the aggregate capital grows as opposed to its variable part, and so does the part of the surplus-value that is consumed as revenue. There is accordingly an increased demand for menial servants. (Ricardo, *Principles*, p. 473.)

76. 'Property ... is essential to preserve the common unskilled worker from falling into the condition of a piece of machinery, bought at the *minimum* market price at which it can be produced, that is at which labourers can be got to exist and propagate their species, to which he is *invariably* reduced sooner or later, when the interests of capital and labour are quite distinct, and are left to adjust themselves under the sole operation of the law of supply and demand' (Samuel Laing, *National Distress*, London, 1844, p. 46).

IRELAND. EMIGRATION

77. In so far as the real increase or decrease of the working population could exert any perceptible influence on the labour market over the ten-year industrial cycle, this could happen only in England and we therefore take it as our model. For the capitalist mode of production is fully developed in England, unlike on the Continent, where it still functions on the foundations of an agricultural economy alien to it. We may therefore consider in isolation the influence which the need of capital to expand exercises upon the expansion or contraction of emigration. We should begin by noting that the emigration of capital, i.e. of that part of annual revenue which is invested abroad, particularly in the colonies and the United States of America, is far greater in proportion to the annual accumulation fund than is the number of emigrants in proportion to the annual growth in the population. And indeed a part does in fact follow the capital abroad. Furthermore, emigration from England consists if we consider its principal part, the agricultural sector, not of working men, but of tenant-farmers' sons, etc. Hitherto it was more than made good by immigration from Ireland. The periods of stagnation and crisis where the impulse to emigrate is at its height are identical with those periods in which more surplus capital is sent abroad, and conversely, the periods in which emigration declines correspond to those where the emigration of surplus capital is in decline. Hence the absolute relation between labour-power and the capital *employed* in the country is largely unaffected by the fluctuations in emigration. If emigration from England were really to swell to serious dimensions in relation to the annual growth in the population, it would spell the end of its dominance of the world market. The Irish emigration since 1848 has robbed the Malthusians of all their hopes and expectations. In the first place, they had declared that an emigration on a scale that exceeded the growth of the population was an impossibility. The Irish solved the problem despite their poverty. People who have already emigrated for the most part send back each year the means to enable those who are left behind to emigrate in their turn. Secondly, however, these gentlemen had prophesied that the famine that carried off a million and the exodus that succeeded it would have the same effect in Ireland as the Black Death in England in the mid fourteenth century. Exactly the opposite has occurred. Production has declined faster than the population, and

so have the means of occupying the agricultural labourers, even though their wages are no higher now, if we take the differences in the price of necessaries into account, than they were in 1847. The population, however, has diminished from 8 million to around 4½ million in 15 years. It is true, indeed, that the production of cattle has increased somewhat, and Lord Dufferin, who wishes to transform Ireland into pasture land for sheep, is quite right when he says that the people are still far too numerous. The Irish, meanwhile, take not only their bones to America but also themselves, and the terrible threat of the *Exoriare aliquis ultor** will one day be fulfilled on the other side of the Atlantic.

If we examine the last two years 1864 and 1865 we discover the following figures for the chief crops:

	1864 (qrs)	1865 (qrs)	Decrease
Wheat	875,782	826,783	48,999
Oats	7,826,332	7,659,727	166,605
Barley	761,909	732,017	29,892
Bere	15,160	13,989	1,171
Potatoes	4,312,388	3,865,990	446,398
Turnips	3,467,659	3,301,683	165,976
Flax	64,506	39,561	29,945

(The official *Agricultural Statistics of Ireland*, Dublin, 1866, p. 4.)

This does not prevent individuals from enriching themselves at the cost of ruining the country as a whole. For example, the number of persons whose annual income ranged between £900 and £1,000 was 59 in 1864 and 66 in 1865; for those between £1,000 and £2,000, 315 in 1864 and 342 in 1866. Other incomes were as follows:

	1864	1865
Incomes between £3,000–4,000	46	50
£4,000–5,000	19	28
£5,000–10,000	30	44
£10,000–50,000	23	25

And there were three persons each of whom had £87,706 and three each of whom had £91,509 (*Income and Property Tax*

---

* '*Exoriare aliquis nostris ex ossibus ultor*' (Virgil, *Aeneid*, Bk IV, line 625). 'May an avenger one day arise from our bones.'

Returns, 7 August 1866).* Lord Dufferin, who is himself one of the 'supernumeraries', finds, rightly, that Ireland still has far too many inhabitants.

[EXPROPRIATION AND DEPOPULATION IN EASTERN GERMANY DURING THE EIGHTEENTH CENTURY]

'Not until the reign of Frederick II were Prussian subjects (peasants) granted security of tenure and the right to inherit their land in the majority of the provinces of the Kingdom. The decree authorizing this helped put an end to a grievance on the part of the rural population that was threatening to *depopulate* the countryside. For earlier in the (eighteenth) century, ever since the landlords had begun to concentrate their efforts on *raising the yield of their properties*, they found it to their advantage *to drive out many of their subjects and to add their fields to their own estates.* The people thus expropriated, having no home of their own, became destitute; those who remained were now overwhelmed by the burdens imposed on them, since the lords of the manor now required them to till the fields that had formerly been worked by the tenants whose labour had previously greatly facilitated the cultivation of the lords' fields. This process of enclosure, known as "*Bauernlegen*", was especially severe in the *eastern parts of Germany.* When Frederick II conquered Silesia there were many thousands of farms without farmers; the huts lay in ruins, the fields were in the hands of the lords of the manor. *All confiscated land* had to be reorganized, farmers had to be found, cattle and equipment provided and the land redistributed among the peasantry with the right of tenure and to pass the land on to their heirs. In *Rügen*, even during the boyhood of Ernst Moritz Arndt, the same abuses led to uprisings on the part of the rural populace, troops had to be sent, rebels imprisoned: the peasants then sought to avenge themselves, they ambushed individual noblemen and murdered them. Similarly, in the *Electorate of Saxony*, the same abuses led to an uprising as late as 1790' (Gustav Freytag).‡

What the noble feelings of the feudal lords really amounted to was made perfectly clear here!†

*The more detailed analysis of these statistics in *Capital* makes it clear that three persons each received an average of £87,606 in 1864 and an average of £91,509 in 1865. See above, p. 859.

‡Freytag, op. cit., pp. 38–9.

[PROPERTY AND CAPITAL]

Although the formation of capital and the capitalist mode of production are essentially founded not merely on the abolition of feudal production but also on the *expropriation of the* peasantry, craftsmen and in general of the mode of production based on the *private ownership by the immediate producer of his conditions of production*; although, once capitalist production has been introduced, it continues to develop at the same rate as that private property and the mode of production based on it is destroyed, so that those immediate producers are expropriated in the name of the *concentration of capital* (centralization); although the subsequent systematic repetition of the process of *expropriation* in the 'clearing of estates' is in part the act of violence that *inaugurates* the capitalist mode of production – although all this is the case, both the *theory of capitalist production* (political economy, philosophy of law, etc.) and the capitalist himself in *his own mind* is pleased to confuse his mode of property and appropriation, which is based on the expropriation of the immediate producer in its origins, and on the acquisition of the labour of others in its further progress, with its opposite: with a mode of production that presupposes that the *immediate producer privately owns his own conditions of production* – a premiss which would actually render capitalist production in agriculture and manufacture, etc. impracticable. In consequence he regards every attack on this latter *form of appropriation* as an attack on the former and indeed as an attack on *property as such.* Not unnaturally, the capitalist always finds it extremely difficult to represent the expropriation of the working masses as the precondition of property based on labour. (Incidentally, in private property of every type the *slavery* of the members of the family at least is always implicit since they are made use of and exploited by the head of the family.) Hence, the general juridical notion from Locke to Ricardo is always that of *petty-bourgeois ownership*, while the relations of production they describe belong to the *capitalist mode of production.* What makes this possible is the relationship of *buyer* and *seller* which *formally* remains the same in both cases. In all these writers the following dualism is apparent:

(1) *Economically* they are opposed to *private property based on labour*; they present the advantages of the *expropriation of the masses* and the *capitalist mode of production*;

(2) *Ideologically* and *juridically* the ideology of private property founded on labour is transferred without more ado to property founded on the *expropriation of the immediate producers.*

79. Thus, for example, the talk of eliminating present burdens by means of government debts which put them on the shoulders of future generations. When B lends A goods either in reality or in appearance, A can give him a promissory note on the *products of the future,* just as there are poets and composers of the future. But A and B together never consume an atom of the produce of the future. Every age must pay its own way. A worker, on the other hand, is able to spend in advance this year the labour of the next three.

'In pretending to stave off the expenses of the present hour to a future day, in pretending that you can burthen posterity to supply the wants of the existing generation', the absurd claim is made 'that you can consume what does not yet exist, that you can feed on provisions before their seeds have been sown in the earth ... All the wisdom of our statesmen will have ended in a great transfer of property from one class of persons to another, in creating an enormous fund for the rewards of jobs and peculation' (Piercy Ravenstone, M.A., *Thoughts on the Funding System and Its Effects,* London, 1824, pp. 8, 9).

THE COLLIERS

73. What the colliers' dependence on the exploiters for their homes means in practice can be seen in any strike. For example, the strike in Durham in November 1863. The people were evicted, wives and children included, in the harshest weather; and their furniture was put into the street. Their first problem then was to find shelter from the cold nights. A large number slept in the open; some broke into their evacuated dwellings and occupied them during the night. The next day the mine-owners had the doors and windows barred and nailed up, to deprive the evicted people of the luxury of sleeping through ice-cold nights on the bare floors of the empty cottages. The people then took refuge in setting up wooden cabins, and wigwams made of peat, but these were torn down by the owners of the fields they had entered. A host of children died or were broken during this campaign of labour against capital. (*Reynolds' Newspaper,* 29 November 1863.)

Quotations in Languages other than English and German

p. 126, n. 6 'La valeur consiste dans le rapport d'échange qui se trouve entre telle chose et telle autre, entre telle mesure d'une production et telle mesure d'une autre.'

p. 130, n. 10 'Toutes les productions d'un même genre ne forment proprement qu'une masse, dont le prix se détermine en général et sans égard aux circonstances particulières.'

p. 133, n. 13 'Tutti i fenomeni dell'universo, sieno essi prodotti della mano dell'uomo, ovvero delle universali leggi della fisica, non ci danno idea di attuale creazione, ma unicamente di una modificazione della materia. Accostare e separare sono gli unici elementi che l'ingegno umano ritrova analizzando l'idea della riproduzione; e tanto è riproduzione di valore' (. . .) 'e di ricchezza se la terra, l'aria e l'acqua ne' campi si trasmutino in grano, come se colla mano dell'uomo il glutine di un insetto si trasmuti in velluto ovvero alcuni pezzetti di metallo si organizzino a formare una ripetizione.'

p. 175, n. 35 'Les économistes ont une singulière manière de procéder. Il n'y a pour eux que deux sortes d'institutions, celles de l'art et celles de la nature. Les institutions de la féodalité sont des institutions artificielles, celles de la bourgeoisie sont des institutions naturelles. Ils ressemblent en ceci aux théologiens, qui eux aussi établissent deux sortes de religions. Toute religion qui n'est pas la leur est une invention des hommes, tandis que leur propre religion est une émanation de dieu. – Ainsi il y a eu l'histoire, mais il n'y en a plus.'

p. 183, n. 6 'I metalli . . . naturalmente moneta.'

p. 184, n. 8 'Il danaro è la merce universale.'

p. 185, n. 10 'L'oro e l'argento hanno valore come metalli anteriore all'essere moneta.'

p. 185, n. 11 'L'argent en' (des denrées) 'est le signe.'

'Comme signe il est attiré par les denrées.'

'L'argent est un signe d'une chose et la représente.'

'L'argent n'est pas simple signe car il est lui-même richesse; il ne représente pas les valeurs, il les équivaut.'

'Qu'aucun puisse ni doive faire doute, que à nous et à notre majesté royale n'appartienne seulement . . . le mestier, le fait, l'état, la provision et toute l'ordonnance des monnaies, de donner tel cours, et pour tel prix comme il nous plaît et bon nous semble.'

p. 194, n. 9 'Le monete le quali oggi sono ideali sono le più antiche d'ogni nazione, e tutte furono un tempo reali, e perchè erano reali con esse si contava.'

p. 196, n. 14 'Ou bien, il faut consentir à dire qu'une valeur d'un million en argent vaut plus qu'une valeur égale en marchandises,' and hence 'qu'une valeur vaut plus qu'une valeur égale'.

p. 203, n. 17 'Toute vente est achat.' 'Vendre est acheter.'

p. 204, n. 18 'Le prix d'une marchandise ne pouvant être payé que par le prix d'une autre marchandise.'

p. 204, n. 19 'Pour avoir cet argent, il faut avoir vendu.'

p. 205, n. 21 'Si l'argent représente, dans nos mains, les choses que nous pouvons désirer d'acheter, il y représente aussi les choses que nous avons vendues pour . . . cet argent.'

p. 206, n. 22 'Il y a donc . . . quatre termes et trois contractants, dont l'un intervient deux fois.'

p. 212, n. 26 'Il' (l'argent) 'n'a d'autre mouvement que celui qui lui est imprimé par les productions.'

p. 215, n. 27 'Ce sont les productions qui le' (l'argent) 'mettent en mouvement et le font circuler . . . La célérité de son mouvement' (i.e. de l'argent) 'supplée à sa quantité. Lorsqu'il en est besoin, il ne fait que glisser d'une main dans l'autre sans s'arrêter un instant.'

p. 221, n. 31 'Si l'on compare la masse de l'or et de l'argent qui est dans le monde, avec la somme des marchandises qui y sont, il est certain que chaque denrée ou marchandise, en particulier, pourra être comparée à une certaine portion . . . de l'autre. Supposons qu'il n'y ait qu'une seule denrée ou marchandise dans le monde, ou qu'il n'y ait qu'une seule qui s'achète, et qu'elle se divise comme l'argent: cette partie de cette marchandise répondra à une partie de la masse de l'argent; la moitié du total de l'une à la moitié du total de l'autre etc. . . . l'établissement du prix des choses dépend toujours fondamentalement de la raison du total des choses au total des signes.'

p. 227, n. 37 'Une richesse en argent n'est que . . . richesse en productions, converties en argent.'

'Une valeur en productions n'a fait que changer de forme.'

p. 230, n. 43 'οὐδὲν γὰρ ἀνθρώποισιν οἷον ἄργυρος κακὸν νόμισμ' ἔβλαστε τοῦτο καὶ πολεις πορθεῖ, τόδ' ἄνδρας ἐξανίστησιν δόμων. τόδ' ἐκδιδάσκει καὶ παραλλάσσει φρένας χρηστὰς πρὸς αἰσχρὰ πράγμαθ' [ἵστασθαι βροτῶν.]

[πανουργίας δ'ἔδειξεν] ἀνθρώποις ἔχειν καὶ παντὸς ἔργου δυσσέβειαν εἰδέναι.'

p. 230, n. 44 ''Ἐλπιζούσης τής πλεονεξίας ἀναξειν ἐκ των μυκῶν τῆς γῆς αὐτόν τὸν πλούτωνα.'

p. 231, n. 45 'Accrescere quanto più si può il numero de' venditori d'ogni merce, diminuire quanto più si può il numero dei compratori, questi sono i cardini sui quali si raggirano tutte le operazioni di economia politica.'

p. 239, n. 56 'L'argent . . . est devenu le bourreau de toutes les choses.' . . . 'alambic qui a fait évaporer une quantité effroyable de biens et de denrées pour faire ce fatal précis.' 'L'argent déclare la guerre . . . à tout le genre humain.'

p. 243, n. 63 'L'argent se partage entre les nations relativement au besoin qu'elles en ont . . . étant toujours attiré par les productions.'

p. 248, n. 2 'Avec de l'argent on achète des marchandises, et avec des marchandises on achète de l'argent.'

p. 251, n. 4 'On n'échange pas de l'argent contre de l'argent.'
'Le commerce est un jeu . . . et ce n'est pas avec des gueux qu'on peut gagner. Si l'on gagnait long-temps en tout avec tous, il faudrait rendre de bon accord les plus grandes parties du profit, pour recommencer le jeu.'

p. 254, n. 8. 'Il mercante non conta quasi per niente il lucro fatto, ma mira sempre al futuro.'

p. 255, n. 11 'Questo infinito che le cose non hanno in progresso, hanno in giro.'

p. 255, n. 12 'Ce n'est pas la matière qui fait le capital, mais la valeur de ces matières.'

p. 260, n. 3 'Que l'une de ces deux valeurs soit argent, ou qu'elles soient toutes deux marchandises usuelles, rien de plus indifférent en soi.'

p. 260, n. 4 'Ce ne sont pas les contractants qui prononcent sur la valeur; elle est décidée avant la convention.'

p. 261, n. 6 'L'échange devient désavantageux pour l'une des parties, lorsque quelque chose étrangère vient diminuer ou exagérer le prix: alors l'égalité est blessée, mais la lésion procède de cette cause et non de l'échange.'

p. 261, n. 7 'L'échange est de sa nature un contrat d'égalité qui se fait de valeur pour valeur égale. Il n'est donc pas un moyen de s'enrichir, puisque l'on donne autant que l'on reçoit.'

p. 262, n. 9 'Dans la société formée il n'y a pas de surabondant en aucun genre.'

p. 263, n. 12 'Si l'on est forcé de donner pour 18 livres une quantité de telle production qui en valait 24, lorsqu'on employera ce même argent à acheter, on aura également pour 18 l. ce que l'on payait 24.'

p. 263, n. 13 'Chaque vendeur ne peut donc parvenir à renchérir habituellement ses marchandises, qu'en se soumettant aussi à payer habituellement plus cher les marchandises des autres vendeurs; et par la même raison, chaque consommateur ne peut . . . payer habituellement moins cher ce qu'il achète, qu'en se soumettant aussi à une diminution semblable sur le prix des choses qu'il vend.'

p. 266, n. 18 'L'échange qui se fait de deux valeurs égales n'augmente ni ne diminue la masse des valeurs subsistants dans la société. L'échange de deux valeurs inégales . . . ne change rien non plus à la somme des valeurs sociales, bien qu'il ajoute à la fortune de l'un ce qu'il ôte de la fortune de l'autre.' 'On n'achète des produits qu'avec des produits.' 'Les productions ne se paient qu'avec des productions.'

p. 278, n. 12 'Le crédit commercial a dû commencer au moment où l'ouvrier, premier artisan de la production, a pu, au moyen de ses économies, attendre le salaire de son travail jusqu'à la fin de la semaine, de la quinzaine, du mois, du trimestre etc.'

p. 278, n. 13 'L'ouvrier prête son industrie' . . . 'de perdre son salaire . . . l'ouvrier ne transmet rien de matériel.'

p. 298, n. 14 'Cette façon d'imputer à une seule chose la valeur de plusieurs autres' (par example au lin la consommation du tisserand), 'd'appliquer, pour ainsi dire, couche sur couche, plusieurs valeurs sur une seule, fait que celle-ci grossit d'autant . . . Le terme d'addition peint très-bien la manière dont se forme le prix des ouvrages de main d'oeuvre; ce prix n'est qu'un total de plusieurs valeurs consommées et additionnées ensemble; or, additionner n'est pas multiplier.'

p. 318, n. 8 'Toutes les productions d'un même genre ne forment proprement qu'une masse, dont le prix se détermine en général et sans égard aux circonstances particulières.'

p. 342, n. 5 'Si le manouvrier libre prend un instant de repos, l'économie sordide qui le suit des yeux avec inquiétude, prétend qu'il la vole.'

p. 430, n. 1 'Le simple ouvrier, qui n'a que ses bras et son industrie, n'a rien qu'autant qu'il parvient à vendre à d'autres sa peine . . . En tout genre de travail il doit arriver et il arrive en effet, que le salaire de l'ouvrier se borne à ce qui lui est nécessaire pour lui procurer la subsistance.'

p. 431, n. 2 'Quando si perfezionano le arti, che non è altro che la scoperta di nuove vie, onde si possa compiere una manufattura con menogente o (che è lo stesso) in minor tempo di prima.' 'L'économie sur les frais de production ne peut être autre chose que l'économie sur la quantité de travail employé pour produire.'

p. 438, n. 8 'Ces speculateurs si économes du travail des ouvriers qu'il faudrait qu'ils payassent.'

p. 444, n. 8 'On doit encore remarquer que cette division partielle du travail peut se faire quand même les ouvriers sont occupés d'une même besogne. Des maçons par exemple, occupés de faire passer de mains en mains des briques à un échafaudage supérieur, font tous la même besogne, et pourtant il existe parmi eux une espèce de division de travail, qui consiste en ce que chacun d'eux fait passer la brique par un espace donné, et que tous ensemble la font parvenir beaucoup plus promptement à l'endroit marqué qu'ils ne feraient si chacun d'eux portait sa brique séparément jusqu'à l'échafaudage supérieur.'

p. 445, n. 9 'Est-il question d'exécuter un travail compliqué, plusieurs choses doivent être faites simultanément. L'un en fait une pendant que l'autre en fait une autre, et tous contribuent à l'effet qu'un seul homme n'aurait pu produire. L'un rame pendant que l'autre tient le gouvernail, et qu'un troisième jette le filet ou harponne le poisson, et la pêche a un succès impossible sans ce concours.'

p. 447, n. 13 'La forza di ciascuno uomo è minima, ma la riunione delle minime forze forma una forza totale maggiore anche della somma delle forze medesime fino a che le forze per essere riunite possono diminuire il tempo ed accrescere lo spazio della lore azione.'

p. 456, n. 1 '... est toute patriarcale; elle emploie beaucoup de femmes et d'enfants, mais sans les épuiser ni les corrompre; elle les laisse dans leurs belles vallées de la Drôme, du Var, de l'Isère, de Vaucluse, pour y élever des vers et dévider leurs cocons; ... jamais elle n'entre dans une véritable fabrique. Pour être aussi bien observé ... le principe de la division du travail, s'y revêt d'un caractère spécial. Il y a bien des dévideuses, des moulineurs, des teinturiers, des encolleurs, puis des tisserands; mais ils ne sont pas réunis dans un même établissement, ne dépendent pas d'un même maître; tous ils sont indépendants.'

p. 471, n. 25 'Nous rencontrons chez les peuples parvenus à un certain degré de civilisation trois genres de divisions d'industrie: la première, que nous nommons générale, amène la distinction des producteurs en agriculteurs, manufacturiers et commerçans, elle se rapporte aux trois principales branches d'industrie nationale; la seconde, qu'on pourrait appeler spéciale, est la division de chaque genre d'industrie en espèces . . . la troisième division d'industrie, celle enfin qu'on devrait qualifier de division de la besogne ou du travail proprement dit, est celle qui s'établit dans les arts et les métiers séparés . . . qui s'établit dans la plupart des manufactures et des ateliers.'

p. 477, n. 36 'On peut ... établir en règle générale, que moins l'autorité préside à la division du travail dans l'intérieur de la société, plus la division du travail se développe dans l'intérieur de l'atelier, et plus elle y est soumise à l'autorité d'un seul. Ainsi l'autorité dans l'atelier et celle dans la société, par rapport à la division du travail, sont en raison inverse l'une de l'autre.'

p. 481, n. 39 'La concentration des instruments de production et la division du travail sont aussi inséparables l'une de l'autre que le sont, dans le régime politique, la concentration des pouvoirs publics et la division des intérêts privés.'

p. 482, n. 42 'L'ouvrier qui porte dans ses bras tout un métier, peut aller partout exercer son industrie et trouver des moyens de subsister: l'autre ... n'est qu'un accessoire qui, séparé de ses confrères, n'a plus ni capacité, ni indépendance, et qui se trouve forcé d'accepter la loi qu'on juge à propos de lui imposer.'

p. 486, n. 54 'Ciascuno prova coll'esperienza, che applicando la mano e l'ingegno sempre allo stesso genere di opere e di produtti, egli più facili, più abbondanti e migliori ne trova i resultati, di quello che se ciascuno isolatamente le cose tutte a sé necessariamente soltanto facesse... Divendosi in tal maniera per la comune e privata utilità gli uomini in varie classe e condizioni.'

p. 513, n. 27 'Il est possible ... de parvenir à des connaissances fort utiles à la vie, et qu'au lieu de cette philosophie spéculative qu'on enseigne dans les écoles, on en peut trouver une pratique, par laquelle, connaissant la force et les actions du feu, de l'eau, de l'air, des astres, et de tous les autres corps qui nous environnent, aussi distinctement que nous connaissons les divers métiers de nos artisans, nous les pourrions employer en même façon à tous les usages auxquels ils sont propres, et ainsi nous rendre comme maîtres et possesseurs de la nature . . . contribuer au perfectionnement de la vie humaine.'

p. 548, n. 5 'Un homme s'use plus vite en surveillant quinze heures par jour l'évolution uniforme d'un mécanisme, qu'en exerçant dans le même espace de temps, sa force physique. Ce travail de surveillance, qui servirait peut-être d'utile gymnastique à l'intelligence, s'il n'était pas trop prolongé, détruit à la longue, par son excès, et l'intelligence et le corps même.'

p. 555, n. 14 'In hac urbe . . . ante hos viginti circiter annos instrumentum quidam invenerunt textorium, quo solus quis plus panni et facilius conficere poterat, quam plures aequali tempore. Hinc turbae ortae et querulae textorum, tandemque usus hujus instrumenti a magistratu prohibitus etc.'

p. 556, n. 16 'Je considère donc les machines comme des moyens d'augmenter (virtuellement) le nombre des gens industrieux qu'on n'est pas obligé de nourrir... En quoi l'effet d'une machine diffère-t-il de celui de nouveaux habitants?'

p. 575, n. 48 'Les classes condamnées à produire et à consommer diminuent, et les classes qui dirigent le travail, qui soulagent, consolent et éclairent toute la population, se multiplient . . . et s'approprient tous les bienfaits qui résultent de la diminution des frais du travail, de l'abondance des productions et du bon marché des consommations. Dans cette direction, l'espèce humaine s'élève aux plus hautes conceptions du génie, pénètre dans les profondeurs mystérieuses de la religion, établit les principes salutaires de la morale' (de 's'approprier tous les bienfaits etc.'), 'les lois tutélaires de la liberté' (... liberté pour 'les classes condamnées à produire'?) 'et du pouvoir, de l'obéissance et de la justice, du devoir et de l'humanité.'

p. 649, n. 6 'Le solstice est le moment de l'année où commence la crue du Nil, et celui que les Égyptiens ont dû observer avec le plus d'attention . . . C'était cette année tropique qu'il leur importait de marquer pour se diriger dans leurs opérations agricoles. Ils durent donc chercher dans le ciel un signe apparent de son retour.'

p. 650, n. 9 'Chaque travail doit... laisser un excédant.'

p. 672, n. 4 '... une richesse indépendante et disponible, qu'il n'a point achetée et qu'il vend.'

p. 676, n. 4 'Il a fallu convenir ... que toutes les fois qu'il échangerait du travail fait contre du travail à faire, le dernier' (le capitaliste) 'aurait une valeur supérieure au premier' (le travailleur).

p. 677, n. 6 ' "Le travail est dit valoir, non pas en tant que marchandise lui-même, mais en vue des valeurs qu'on suppose renfermées puissanciellement en lui. La valeur du travail est une expression figurée etc..." Dans le travail-marchandise, qui est d'une réalité effrayante, il ne voit qu'une ellipse grammaticale. Donc toute la société actuelle, fondée sur le travail-marchandise, est désormais fondée sur une licence poétique, sur une expression figurée. La société veut-elle "éliminer tous les inconvénients" qui la travaillent, eh bien! qu'elle élimine les termes malsonnants, qu'elle change de langage, et pour cela elle n'a qu'à s'adresser à l'Académie pour lui demander une nouvelle édition de son dictionnaire.'
'C'est ce qu'une chose vaut.' 'La valeur d'une chose exprimée en monnaie.' And why has 'le travail de la terre ... une valeur? Parce qu'on y met un prix.'

p. 694, n. 4 'Le salaire peut se mesurer de deux manières; ou sur la durée du travail, ou sur son produit.'

p. 697, n. 12 'Combien de fois n'avons-nous pas vu, dans certains ateliers, embaucher, beaucoup plus d'ouvriers que ne demandait le travail à mettre en main? Souvent, dans la prévision d'un travail aléatoire, quelquefois même imaginaire, on admet des ouvriers: comme on les paie aux pièces, on se dit qu'on ne court aucun risque, parce que toutes les pertes de temps seront à la charge des inoccupés.'

p. 723, n. 18 'L'ouvrier demandait de la subsistance pour vivre, le chef demandait du travail pour gagner.'

p. 728, n. 4 'Le travail primitif auquel son capital a dû sa naissance.'

p. 735, n. 17 'Objets de faste et de somptuosité' dont 'le tems a grossi l'accumulation' et que 'les loix de la propriété ont rassemblés dans une seule classe de la société.'

p. 738, n. 20 'Il est impossible de résoudre le prix nécessaire dans ses éléments les plus simples.'

p. 742, n. 25 'Les épargnes des riches se font aux dépens des pauvres.'

p. 745, n. 32 'La privation que s'impose le capitaliste, en prêtant... ses instruments de production au travailleur au lieu d'en consacrer la valeur à son propre usage, en la transformant en objets d'utilité ou d'agrément.'

p. 745, n. 33 'La conservation d'un capital exige ... un effort constant pour résister à la tentation de le consommer.'

p. 755, n. 48 'Quant à la difficulté qu'élève Mr Ricardo en disant que, par des procédés mieux entendus, un million de personnes peuvent produire deux fois, trois fois autant de richesses, sans produire plus de valeurs, cette difficulté n'est pas une lorsque l'on considère, ainsi qu'on le doit, la production comme un échange dans lequel on donne les services productifs de son travail, de sa terre, et de ses capitaux, pour obtenir des produits. C'est par le moyen de ces services productifs que nous acquérons tous les produits qui sont au monde . . . Or . . . nous sommes d'autant plus riches, nos services productifs ont d'autant plus de valeur, qu'ils obtiennent dans l'échange appelé production, une plus grande quantité de choses utiles.'

'. . . parce que la concurrence les' (les producteurs) 'oblige à donner les produits pour ce qu'ils leur coûtent.'

'Telle est, monsieur, la doctrine bien liée sans laquelle il est impossible, je le déclare, d'expliquer les plus grandes difficultés de l'économie politique et notamment, comment il se peut qu'une nation soit plus riche lorsque ses produits diminuent de valeur, quoique la richesse soit de la valeur.'

'. . . Si vous trouvez une physionomie de paradoxe à toutes ces propositions, voyez les choses qu'elles expriment, et j'ose croire qu'elles vous paraîtront fort simples et fort raisonnables.'

p. 764, n. 1 'À égalité d'oppression des masses, plus un pays a de prolétaires et plus il est riche.'

p. 797, n. 22 'Iddio fa che gli uomini che esercitano mestieri di prima utilità nascono abbondantemente.'

p. 799, n. 23 'De jour en jour il devient donc plus clair que les rapports de production dans lesquels se meut la bourgeoisie n'ont pas un caractère uni, un caractère simple, mais un caractère de duplicité; que dans les mêmes rapports dans lesquels se produit la richesse, la misère se produit aussi; que dans les mêmes rapports dans lesquels il y a développement des forces productives, il y a une force productive de répression; que ces rapports ne produisent la richesse bourgeoise, c'est à dire la richesse de la classe bourgeoise, qu'en anéantissant continuellement la richesse des membres intégrants de cette classe et en produisant un prolétariat toujours croissant.'

p. 800, n. 24 'In luoco di progettar sistemi inutili per la felicità de' popoli, mi limiterò a investigare la ragione della loro infelicità.'

p. 877, n. 2 'Le paysan y' (en Silésie) 'est serf.' 'On n'a pas pu encore engager les Silésiens au partage des communes, tandis que dans la nouvelle Marche, il n'y a guère de village où ce partage ne soit exécuté avec le plus grand succès.'

p. 894, n. 33 'Le lin fait donc une des grandes richesses du cultivateur dans le Nord de l'Allemagne. Malheureusement pour l'espèce humaine, ce n'est qu'une ressource contre la misère, et non un moyen de bien-être. Les impôts directs, les corvées, les servitudes de tout genre, écrasent le cultivateur allemand, qui paie encore des impôts indirects dans tout ce qu'il achète . . . et pour comble de ruine, il n'ose pas vendre ses productions où et comme il le veut; il n'ose pas acheter ce dont il a besoin aux marchands qui pourraient le lui livrer au meilleur prix. Toutes ces causes le ruinent insensiblement, et il se trouverait hors d'état de payer les impôts directs à l'échéance sans la filerie; elle lui offre une ressource, en occupant utilement sa femme, ses enfants, ses servants, ses valets, et lui-même: mais quelle pénible vie, même aidée de ce secours! En été, il travaille comme un forçat au labourage et à la récolte; il se couche à neuf heures et se lève à deux, pour suffire aux travaux; en hiver il devrait réparer ses forces par un plus grand repos; mais il manquera de grains pour le pain et les semailles, s'il se défait des denrées qu'il faudrait vendre pour payer les impôts. Il faut donc filer pour suppléer à ce vide . . . il faut y apporter la plus grande assiduité. Aussi le paysan se couche-t-il en hiver à minuit, une heure, et se lève à cinq ou six; ou bien il se couche à neuf, et se lève à deux, et cela tous les jours de sa vie si ce n'est le dimanche. Cet excès de veille et de travail usent la nature humaine, et de là vient qu'hommes et femmes vieillissent beaucoup plutôt dans les campagnes que dans les villes.'

p. 904, n. 6 'L'anéantissement de toutes espèces de corporations du même état et profession étant l'une des bases fondamentales de la constitution française, il est défendu de les rétablir de fait sous quelque prétexte et sous quelque forme que ce soit . . .' '[Si] des citoyens attachés aux mêmes professions, arts et métiers prenaient des délibérations, faisaient entre eux des conventions tendantes à refuser de concert ou à n'accorder qu'à un prix déterminé le secours de leur industrie ou de leurs travaux, les dites délibérations et conventions . . . seront déclarées inconstitutionelles, attentatoires à la liberté et à la déclaration des droits de l'homme etc.'

p. 907, n. 3 'C'est li compte que messire Jacques de Thoraisse, chevalier chastelain sor Besançon rent es seigneur tenant les comptes à Dijon pour monseigneur le duc et comte de Bourgoigne, des rentes appartenant à la dite chastellenie, depuis XXVe jour de décembre MCCCLIX jusqu'au XXVIIIe jour de décembre MCCCLX.'

p. 909, n. 3 'Je permettrai . . . que vous ayez l'honneur de me servir, à condition que vous me donnez le peu qui vous reste pour la peine que je prends de vous commander.'

p. 920, n. 8 'Si les Tartares inondaient l'Europe aujourd'hui, il faudrait bien des affaires pour leur faire entendre ce que c'est un financier parmi nous.'

p. 922, n. 9 'Pourquoi aller chercher si loin la cause de l'éclat manufacturier de la Saxe avant la guerre? Cent quatre-vingt millions de dettes faites par les souverains!'

p. 928, n. 1 'Nous sommes . . . dans une condition tout-à-fait nouvelle de la société . . . nous tendons à séparer . . . toute espèce de propriété d'avec toute espèce de travail.'

p. 937, n. 16 'Dans les colonies où l'esclavage a été aboli sans que le travail forcé se trouvait remplacé par une quantité équivalente de travail libre, on a vu s'opérer la contrepartie du fait qui se réalise tous les jours sous nos yeux. On a vu les simples travailleurs exploiter à leur tour les entrepreneurs d'industrie, exiger d'eux des salaires hors de toute proportion avec la part légitime qui leur revenait dans le produit. Les planteurs, ne pouvant obtenir de leurs sucres un prix suffisant pour couvrir la hausse de salaire, ont été obligés de fournir l'excédant, d'abord sur leurs profits, ensuite sur leurs capitaux mêmes. Une foule de planteurs ont été ruinés de la sorte, d'autres ont fermé leurs ateliers pour échapper à une ruine imminente . . . Sans doute, il vaut mieux voir périr des accumulations de capitaux, que des générations d'hommes . . . mais ne vaudrait-il pas mieux que ni les uns ni les autres périssent?'

p. 938, n. 20 'C'est, ajoutez-vous, grâce à l'appropriation du sol et des capitaux que l'homme, qui n'a que ses bras, trouve de l'occupation, et se fait un revenu . . . c'est au contraire, grâce à l'appropriation individuelle du sol qu'il se trouve des hommes n'ayant que leurs bras . . . Quand vous mettez un homme dans le vide, vous vous emparez de l'atmosphère. Ainsi faites-vous, quand vous vous emparez du sol . . C'est le mettre dans le vide de richesses, pour ne le laisser vivre qu'à votre volonté.'

Index of Authorities Quoted

[*Titles as given here may differ in detail from those in the text, since the latter follows Marx's own versions.*]

I. BOOKS BY NAMED OR ANONYMOUS AUTHORS

Addington, Stephen, *An Inquiry into the Reasons for and against Inclosing Open Fields*, 2nd edn, London, 1772. 886–7

Note on Previous Editions of the Works of Marx and Engels

Until recently there existed no complete edition of the works of Marx and Engels in any language. The Marx-Engels Institute, under its director D. Riazanov, began to produce such an edition in the late 1920s. For reasons never since made clear, the project did not survive the mid-1930s. However, eleven indispensable volumes did emerge between 1927 and 1935, under the title *Karl Marx – Friedrich Engels: Historisch-Kritische Gesamtausgabe*, commonly referred to as the *MEGA* edition. The *MEGA* contains the works of both men down to 1848, and their correspondence, but nothing more. For the next thirty years, the field was held by the almost inaccessible Russian edition, the Marx-Engels *Sochineniya* (twenty-nine volumes, 1928–46).

Only in 1968 did the East Germans complete the first definitive edition in the German language, the forty-one volume *Marx-Engels Werke* (*MEW*). Until then, the works of Marx and Engels existed only in separate editions and smaller collections on specific themes. For this reason, the translations into English have followed the same pattern – the only general selection being the *Marx-Engels Selected Works* (*MESW*), now expanded to a three-volume edition. Recently, however, the major gaps in the English translations have begun to be filled up. Lawrence and Wishart have produced a complete translation of *Theories of Surplus-Value*, as well as the first adequate translation of *A Contribution to the Critique of Political Economy* and Marx's book on *The Cologne Communist Trial*. They plan to issue a complete English-language edition of even greater scope than the *MEW*, though this will inevitably take many years to complete. The Penguin Classics editions, previously published as the Pelican Marx Library occupy an intermediate position between the *MESW* and, the complete edition. The most important of Marx's larger works, the three volumes of *Capital* and the *Grundrisse*, as well as three volumes of political writings and a volume of early writings are published in Penguin.

Chronology of Works by Marx and Engels

Date[1]	*Author*[2]	*Title*	*English edition*[3]
1843	M	*Critique of Hegel's Doctrine of the State*	P *EW*
1843	M	*On the Jewish Question*	P *EW*
1843–4	M	*A Contribution to the Critique of Hegel's Philosophy of Right. Introduction*	P *EW*
1844	M	*Excerpts from James Mill's* Elements of Political Economy	P *EW*
1844	E	*Outlines of a Critique of Political Economy*	P. Engels
1844	M	*Economic and Philosophical Manuscripts*	P *EW*
1844	M	*Critical Notes on the Article 'The King of Prussia and Social Reform. By a Prussian'*	P *EW*
1844	M & E	*The Holy Family, or a Critique of Critical Critique*	LW 1957
1844–5	E	*Condition of the Working Class in England*	Blackwell 1958

Routledge Frontiers of Political Economy

VALUE, MONEY AND CAPITAL

THE CRITIQUE OF POLITICAL ECONOMY AND CONTEMPORARY CAPITALISM

Guido Starosta, Gastón Caligaris, and
Alejandro Fitzsimons

ROUTLEDGE

Value, Money and Capital

The book presents a high-impact re-reading of core topics in the Marx and Marxist debates including: value theory, the commodity nature of money, complex or skilled labour, the determination of the value of labour-power and the nature of extraordinary surplus value. Drawing on this literature, the book provides original and innovative insights into key controversies in contemporary capitalism such as the increasingly intellectual character of commodity-producing labour, the emergence of global value chains, the relevance of ground-rent bearing commodities, and the specific, uneven developmental dynamics of "resource-rich" countries in the global process of capital accumulation.

Contributing to the renewed vitality of critical studies of the economic works of Karl Marx, this book will be essential reading for all those interested in contemporary debates within Marxism, as well as readers of political economy, economics, development studies and economic sociology.

Guido Starosta is a Professor in the History of Economic Thought at the National University of Quilmes (UNQ) and a member of the National Council of Scientific and Technical Research (CONICET) and of the Centre for Science as Practical Criticism (CICP), in Argentina. His research interests are in the critique of political economy and political economy of development. He is currently investigating economic and political forms of the accumulation of capital in Argentina. He also works on issues of method and subjectivity in the Marxian critique of political economy.

Gastón Caligaris is a Lecturer in the History of Economic Thought at the National University of Quilmes (UNQ) and a member of the National Council of Scientific and Technical Research (CONICET) and of the Centre for Science as Practical Criticism (CICP), in Argentina. His research interests are in agrarian production and the relationship between economy and politics in contemporary Argentine society. Other research interests include dialectical method and value theory in the Marxian critique of political economy.

Alejandro Fitzsimons is a Lecturer in Argentine Economic History at the National University of Buenos Aires (UBA) and a member of the National Council of

Scientific and Technical Research (CONICET) and of the Centre for Science as Practical Criticism (CICP), in Argentina. His most recent research examines the forms of valorisation of capital in the industrial sector, with a regional focus on Latin America. His other research interests include the economic dynamics of capital accumulation in Argentina and general topics of the Marxian critique of political economy.

We would like to dedicate this book to our teacher Juan Iñigo Carrera. Our intellectual debt to him is vast; significantly, we learnt from him that a radically-transformative action organised through objective knowledge is not only possible, but actually necessary.

In memory of Luis Denari, co-founder of the CICP who unflaggingly strived for a fully-conscious revolutionary action.

Introduction 1

1 **The determinations of value as historically-specific social form. Part I: Materiality and social form of abstract labour** 7
  Introduction 7
  'Rubin's dilemma' and the Marxist debate on abstract labour 8
    Situating the contemporary literature on abstract labour 8
    The Wertkritik's idiosyncratic solution to 'Rubin's dilemma' 11
  Abstract labour and value in chapter 1 of Capital 14
    The initial unearthing of abstract labour and value through the analysis of the commodity 14
    From the analysis of the dual character of labour to the synthetic unfolding of the content and form of the value-determinations 20

2 **The determinations of value as historically-specific social form. Part II: Production and circulation** 28
  Introduction 28
  The contemporary 'circulationist' (over)reaction to the naturalistic reading of Capital: *the case of Michael Heinrich 28*
  The immanent social character of human labour and its private form 31
  Critical remarks on some current attempts to overcome the pitfalls of the circulationist value-form approach 35
    Contemporary production-centred approaches to value as a historically-specific social form 35
    Co-constitutive value-form theory 38
  Conclusion 44
  Appendix. Brief remarks on the magnitude of value 46

3 Systematic and historical modes of explanation in the critique of political economy. A methodological contribution to the controversy over the commodity nature of money 56
Introduction 56
Lapavitsas and Ingham on the nature of money 57
The methodological limits of the explanations put forward in the debate 60
The contemporary reality of money 64
The historical genesis of money 70
Conclusion 73

4 Skilled labour and value-production. An alternative approach to a longstanding and unresolved controversy in the critique of political economy 80
Introduction 80
Marx on skilled labour 80
The critiques of Marx's perspective on the 'reduction problem' and the response of Marxists 83
  The critique of the Marxian solution 83
  The 'rise and fall' of the classic Hilferding–Bauer response 83
  The more recent proliferation of novel solutions to the 'reduction problem' 85
Critical assessment of the complex labour debate 86
The determination of complex labour in value-production 91
Conclusion 96

5 Rethinking the determination of the value of labour-power 104
Introduction 104
The 'received wisdom' and its limits 105
Marx's discussion of the most general determinations of the value of labour-power in Capital: *a critical reading 107*
Rethinking Marx's account of the determinations of the value of labour-power 109
The real subsumption of working-class consumption to capital 114
Content and form of the determination of the value of labour-power: on the role of the class struggle 117
A brief illustration 119
Conclusion 121

6 **Extra surplus value from innovation and the Marxian critique of political economy** 124
Introduction 124
The debate over extra surplus value as subsidiary to other Marxist controversies 125
The main arguments in the debate 128
  The 'potentiated labour' thesis 128
  The 'value transfer' thesis 130
Marx on the source of extra surplus value 132
Substance, source and form of extra surplus value 136
Conclusion 142

7 **Cognitive commodities and the growing role of intellectual labour in value-production 147**
Introduction 147
The 'applicability' of the law of value to knowledge-intensive commodities according to 'Cognitive Capitalism' theorists and Marxist economists 149
Material specificity and value of knowledge-intensive commodities 152
Cognitive means of production and the formation of value 154
The economic content and juridical form of cognitive commodities 158
Conclusion 163

8 **A critical look at Global Value Chains Competition and globalisation in contemporary capitalism. The case of the automotive industry** 169
Introduction 169
The qualitative differentiation of individual capitals as the content of the 'chain' form of capitalist competition 170
The changing organisational forms of capitalist competition and the recent configurations of GVCs 175
GVCs and the international fragmentation of the subjective productivity of the working class 179
The global automotive industry in light of the organisational and spatial reconfigurations of GVCs 182
Conclusion 185
Appendix. The rate of profit in the automotive industry 186

Introduction

The last decades have witnessed a renewed interest in Marx's economic works, with a specific focus on the re-examination of their substantive and methodological foundations. In a nutshell, one could say that these novel readings involved a drastic change of angle on the fundamental issues addressed by Marxist political economy *vis-à-vis* those that had prevailed during the greater part of the 20th century. On the one hand, whilst the latter readings had tended one-sidedly and more narrowly to focus on the exploitation of wage-workers by the capitalist class, the new approaches have broadened the view in order also to critically stress the fetishism involved in the constitution of *value* as a historically-specific *social form* assumed by the product of labour.[1] In other words, the main object of critique came to be the historically-specific alienated forms of social mediation in the capitalist mode of production. On the other hand, Marx's critique of political economy was no longer seen as a ready-made, completed theoretical system which only had to be applied to the analysis of contemporary capitalism. Instead, these new readings tended to see it as a conceptual apparatus that should be subject to a *systematic critical reconstruction* and which, in addition, demanded that specific aspects were further developed in a *methodologically-minded* rigorous fashion. Furthermore, some innovative research started to emerge which examined a variety of characteristic features of contemporary capitalism on these novel theoretical and methodological foundations. This showed not only the revitalised scientific potentialities of the Marxian critique of political economy for the comprehension of current affairs but also allowed the critical engagement with other approaches to political economy.

This book will be part and parcel of this wide-ranging resurgence of research in critical Marxist theory, both with regard to the re-examination of its general methodological underpinnings and to the inquiry into the contemporary configuration of the capitalist mode of production. More specifically, we will offer an alternative approach that builds on innovative scholarship that has emerged in the last 20–25 years under the auspices of the Centre for Research as Practical Criticism, based in Buenos Aires, Argentina, and especially the work of the independent scholar Juan Iñigo Carrera. This work, which is only just recently beginning to appear in Anglophone literatures – in part, because it has been developed outside of formal academic structures and networks – represents a thorough re-examination

DOI: 10.4324/9781003201939-1

of Marx's inquiry into the value-form and its dialectical-methodical foundations (Iñigo Carrera 2006; 2013a; 2013b; 2014a; 2014b; 2016; 2021).

This alternative reading of Marx does not simply deal with 'minutiae' but has crucial implications for understanding capitalist society. In stressing the specificity of private labour as the foundation of the historical character of the capitalist mode of production, this approach enables us to uncover how the process of human metabolism is characterised by an automatism subject to laws, whose motion obviously takes shape through the conscious action of individuals, but whose general unity is unconsciously established 'behind their backs' (Starosta 2016a; 2017a; 2017b; 2022). The 'law of value' is the succinct term that refers to the unity of the determinate forms of movement assumed by this alienated mode of existence of social life in all its concrete complexity.

The first three chapters of the book start out with a re-consideration of the simplest economic determinations of the capitalist mode of production, i.e. value and money, against the backdrop of contemporary Marxist debates on the subject. Chapter 1 thus addresses the debate over the materiality and social form of abstract labour as the substance of value and argues that the vast majority of the literature fails to grasp the contradictory unity between the 'transhistorical' physiological quality of abstract labour and its historically-unique socially-mediating function. The chapter also fleshes out an alternative view through a detailed reconstruction of Marx's argument in the first chapter of *Capital*. Succinctly put, we maintain that the historical specificity of value-producing labour does not reside in its abstract character but in the private organisation of its immanent social character, which lies at the basis of abstract labour's historically-specific role.

For its part, Chapter 2 addresses the other major issue which has captured the focus of the contemporary rethinking of the fundamental categories of the critique of political economy, namely: the respective roles of production and circulation in the determination of value as a historically-specific social form. Thus, the second chapter takes issue with the different contemporary variants of the so-called 'circulationist' perspective, whether the more 'extreme' version or the more nuanced views which are at pains to give the sphere of production its due place in the constitution of value as a social form. Moreover, this chapter critically discusses those production-centred alternatives which emphatically reject both the circulationist approach and the asocial stance of value characteristic of the old Ricardian reading. However, we show that these latter views also fail to offer what we think is needed: a rigorous production-centred and non-naturalistic grasp of the value-determinations.

Finally, Chapter 3 provides a methodologically-minded discussion of Marx's account of the genesis of money in the first two chapters of *Capital*. More specifically, it focuses on the connection between systematic development and historical explanation in the dialectical exposition. After reviewing the limitation of the way in which much of the literature articulates these two moments of the investigation, we argue that the explanation of the genesis of money in the exchange of commodities must be provided in fundamentally *systematic* terms. However, in contradistinction to the so-called 'New Dialectics' literature, we submit that historical explanation plays a necessary role in Marx's dialectical exposition in *Capital*. In fact, we show that the account of the crystallisation of the money – form precisely is one of those points 'where historical investigation must enter in'. The key issue, however, is to be clear *why* and *how* the historical mode of explanation must enter the stage.

Based on this rethinking of the general foundations of the critique of political economy, i.e. so-called 'value-theory', the book turns to re-examine an additional series of longstanding controversies among Marxists. Although all these issues deal with more concrete determinations of the capitalist mode of production, they remain at a relatively high level of abstraction and are, in this sense, largely 'theoretical'. They include: the connection between complex labour and value-production (i.e. the reduction of skilled to simple labour) in Chapter 4, several questions around the determinations of the value of labour-power (in particular, the so-called 'historical and moral element') in Chapter 5 and, finally, the nature and source of extra surplus value from innovation in Chapter 6. Various threads hold all these issues together.

In the first place, some of them are problematics which have persisted largely unresolved, yet inexplicably left behind by contemporary Marx scholars, such as the question of the nexus between complex labour and value-production. Secondly and even more curiously, others have remained even *unstated* among Marxists. In the latter case, it is nevertheless possible to find them lurking behind *other* better-known theoretical disputes. For instance, the mechanisms which underlie the flow of extra surplus value into the pockets of capitals operating with above-average productivity of labour have been at stake in many classic debates, such as those over ground-rent, international unequal exchange, the transformation of values into prices of production. Moreover, it is even possible to discern starkly conflicting interpretations about the determinations behind the extraordinary surplus value. Yet, the issue has not been even consciously acknowledged by scholars as being under dispute and, consequently, has not captured the attention which, we think, it deserves for its own sake. Alternatively, as in the case of the determination of the value of labour-power, the question has endured somehow 'muted' by an implicit consensus over an overwhelmingly dominant 'received wisdom' that can be traced back to very early debates among classical Marxists. It has somehow cropped to the surface again recently, but only very timidly and in a derivative fashion within other debates (the so-called 'New Solution' to the transformation problem or those on domestic labour and social reproduction). Finally, in all these cases Marx's own textual legacy on these issues is either ambiguous or simply incomplete and underdeveloped. In this context, the book endeavours to unearth and reconstruct these subterranean controversies whilst offering original insights into the resolution of longstanding gaps in the systematic architecture of the Marxian critique of political economy. In addition, the rigorous resolution of these issues shall prove of utmost importance as intermediate steps which are necessary to address the set of more concrete economic phenomena whose investigation animates the second part of the book.

Two main substantive implications for the analysis of the concrete forms of contemporary capitalism derive from this reading of the Marxian critique of political economy. In the first place, class struggle and state policies are not to be conceived of as independent, self-subsisting factors that externally modify or influence the workings of the law of value. Instead, they need to be grasped as necessary modes of motion through which the law of value further unfolds beyond the strictly economic forms immediately springing from the indirect nature of the social relations of capitalist production (Starosta 2016a; Starosta and Fitzsimons 2018). In the second place, the course and potentialities of capitalist development in each national space should be viewed as the immanent outcome of the *essentially global* unfolding of the 'law of value'. In other words, they must be grounded in the constitution and dynamics of the changing constellation of international division of labour, which in turn results from *the underlying unity of the self-valorisation of value on a world scale* (Caligaris 2016; Charnock and Starosta 2018; Fitzsimons and Starosta 2018; Starosta 2016b; 2019). As will become evident throughout this book, this idiosyncratic perspective on capital as an intrinsically global alienated social relation, specifically differentiated into an *economic content* and *political forms*, offers a more consistent and insightful articulation between Marx's critique of political economy and the analysis of several features of contemporary capitalist society.

Thus, by deciphering the national forms taken by the general content of a historically-specific mode of the reproduction of total (worldwide) society on the basis of the fragmentation of the productive subjectivity of the international working class, and through the development of the automation of large-scale industry within the international division of labour, this approach is able to advance a substantive alternative explanation of the inner relation between global capital accumulation and nationally-uneven development on a world scale. More specifically, those insights will be deployed in the second part of the book with a view to critically scrutinising several phenomena which have been at the centre of both longstanding and more recent scholarly debates over the changing nature of global capitalism, among them: the growing centrality of the cognitive dimension of labour and its implications for value-production (Chapter 7); the constitution and dynamics of global commodity chains in particular branches of the social division of labour (Chapter 8); the development of capitalism in 'resource-rich' countries, whose longstanding historical role in the world market has been to produce ground-rent-bearing commodities (Chapter 9) and the social foundations for the limited potentialities of capitalist development in Latin American countries (Chapter 10). In all these cases, we hope to show that this novel perspective carries with it important and hitherto unacknowledged implications for the study of capitalist society and its historical transformations. Moreover, it involves conclusions that contrast sharply with dominant orthodox and critical theories of global capitalism. Thus, after critically examining the flaws that we find in those literatures, the book shall attempt to demonstrate that those very same features of contemporary capitalism can be elucidated through the unfolding of the specific categories of the critique of political economy as developed in *Capital*, albeit certainly beyond the letter of Marx's texts. As these chapters will hopefully also throw into relief, a key dimension in this alternative explanation of those features of contemporary capitalism lies in the rigorous comprehension of the *methodological* specificity of the Marxian critique of political economy.

Indeed, what we propose is a perspective that seeks to avoid any kind of dualism, exteriority, or 'gap' between so-called 'theory', on the one hand, and the historical development of concrete 'empirical' forms, on the other. In this sense, our approach stands out for its stress on the internal unity between the *content* and *form* of the determinations which constitute its object of research. This form of inquiry not only provides a powerful tool for the systematic critical reconstruction of the 'categorial architecture' of Marx's *Capital* but also offers an illuminating method for the investigation both of aspects which Marx himself did not address or left underdeveloped and of novel concrete phenomena engendered by the historical development of capitalism beyond those that Marx witnessed during his lifetime.

In this sense, this methodological perspective can help overcome the pitfalls of the antinomy that, in our view, characterises a great deal of current economic studies of contemporary society, namely, that between superficial and descriptive empiricism which 'relies […] on the mere semblance as opposed to the law which regulates and determines the phenomena' (Marx 1976, 421–22), on the one hand; and the 'violent abstraction' of approaches that attempt to pierce through immediate appearances in order to discover the inner 'law' that regulates concrete phenomena, but that get bogged down in formal questions of the logical consistency of theoretical constructs, which stand in stark contradiction with the immediate appearance of those phenomena that such theories are meant to explain. By contrast, we take cue from Marx's methodological remarks in the pages just quoted. The key to avoiding this 'apparent contradiction' resides in the systematic critical reconstruction of 'the many intermediate terms' that immanently connect the more abstract and general determinations of phenomena, with the immediate form in which the latter manifest in the 'empirical reality' of contemporary capitalism in all its richness and complexity. In addition, it involves the recognition that those more abstract determinations of capitalist society that Marx presented in *Capital* are not simply subjective or merely ideal constructs that help 'organise' a given empirical content obtained through direct observation or data collection, but are objective aspects that constitute social reality itself.

In sum, we firmly believe that, taken together, these substantive and methodological features of our reading of Marx entail an innovative perspective within contemporary Marxist debates. On this basis, we hope that the book sparks stimulating theoretical and methodological discussions in the critique of political economy, and therefore opens new avenues for further critical research on contemporary capitalism.

Note

1 Throughout this book, we shall use the expression 'value-form' to refer to value as the social form of the product of labour. This is also the case in formulations such as 'the social form of value assumed by the product of labour'. By contrast, we shall use 'the form of value' to refer to exchange-value as the necessary form of appearance of value.

1 The determinations of value as historically-specific social form

Part I: materiality and social form of abstract labour

Introduction

Contemporary Marxian scholarship on *Capital* revolves around the consolidation and refinement of certain themes and perspectives whose origins can be traced back to the late 1970s and early 1980s. These debates around Marx's intellectual legacy have entailed both a methodological and substantive re-examination of his major scientific work. The guiding thread of this reconsideration of the Marxian critique of political economy was the critical reaction against what was seen as the (mis)reading of his 'economic' works along Ricardian and/or Left-Keynesian lines throughout most of the 20th century until the 1970s (as epitomised in the classic texts by Dobb 1968; Meek 1973; Robinson 1969; Sweezy 1970). In contrast to what De Vroey (1982) aptly labelled 'technological' reading to refer to the old orthodoxy, this reappraisal of Marx's theory entailed a renewed emphasis on the historical specificity of capitalist social forms (Murray 2016, 120–55). Although this has led to a wide-ranging rethinking of the structure of Marx's *Capital* as a whole, a great bulk of the discussion has been devoted to shed new light on the simpler determinations of capitalist society and therefore has focused on value, abstract labour and money. The central question was no longer to reduce prices to quantities of labour but, taking cue from Marx's remark in the section on the fetishism of commodities, to comprehend why in capitalist society that content (labour) takes on the social form of value, money and, eventually, capital. In other words, for most of these new readings, Marx's *Capital* was not to be interpreted as a treatise on 'economic theory' but as a critical investigation of the historically-specific reified forms of social mediation of capitalist society. However, beyond this common ground, the reaction to the old Ricardian-Marxist orthodoxy has been very varied and has resulted in the emergence of a great diversity of perspectives on the determinations of value as a social form.[1]

First and foremost, the reappraisal of value as social form has been intimately connected with a rethinking of the nature of abstract labour. The more or less explicit reasoning is deceptively simple: if value is a historically-specific social form, so must be its substance. Against this backdrop, one of the main issues at stake has been the precise sense in which abstract labour should be understood as a capitalist phenomenon. Also, this raised the question of the level of abstraction at

DOI: 10.4324/9781003201939-2

which abstract labour should be more adequately conceptualised; whether it should be treated as already determined at the level of the commodity-form (Murray 2016, 443–64; Smith 2006), or whether it can be fully grasped only from its mode of existence as work exploited by (or subsumed to) capital (Arthur 2001; De Angelis 1996), or whether the process of abstraction should be grasped as fully posited through the process of capitalist reproduction as a whole (Robles Báez 2004).

This debate also ramified into the related issue of the respective roles of production and exchange in the determination of abstract labour and value. At one end of the spectrum, one can find what some critical commentators have labelled the 'circulationist approach' (Mavroudeas 2004), for which abstract labour and value can only acquire objective reality through the exchange of products against money on the market (De Vroey 1982; Eldred and Hanlon 1981; Himmelweit and Mohun 1978; Kay 1999; Reuten 1993; Roberts 2004; Williams 1992). However, certain limitations of the 'circulationist' approach did not remain unnoticed by other scholars and served as the basis for further theoretical developments. The challenge for these alternatives was how to avoid both the 'technological' reading of the value-determinations and the antinomies which arose from seeing value as existing only within circulation. A new variety of approaches emerged which, in their own idiosyncratic way, tried to re-establish the connection between value and the immediate process of production, whilst still seeing the former as a specific social form (Brown 2008; De Angelis 2004; Likitkijsomboon 1995; Mavroudeas 2004; McGlone and Kliman 2004; Postone 1996; Saad-Filho 2002). Finally, some authors seem to offer a middle ground between 'circulationism' and 'production-centred' value theories, in which exchange provides a necessary first moment in the process of social constitution of value that becomes fully grounded when capital sinks into production (Arthur 2001; Bellofiore 2009).

In Chapters 1 and 2 of this book, we subsequently and respectively address these two strands of the Marxist debate. In the present one, we firstly focus on the nature of abstract labour. Based on a critical overview of the main literature, we submit that it fails to grasp the contradictory nexus between materiality and social form of the substance of value. We subsequently flesh out our own alternative view through a detailed reconstruction of Marx's argument in *Capital*. Succinctly put, we argue that the historical specificity of value-producing labour does not reside in its abstract character but in the private organisation of its immanent social character, which imprints upon the 'transhistorical' material quality of abstract labour a historically-unique socially-mediating role.

'Rubin's dilemma' and the Marxist debate on abstract labour

Situating the contemporary literature on abstract labour

The contemporary debate on abstract labour has been heavily marked by the publication of the English translation of Rubin's *Essays on Marx's Theory of Value* in 1972. The relevance of this work was that it had also appeared in an intellectual context dominated by 'Ricardian' (mis)readings of Marx's thought. This is why it became imperative for Rubin to emphasise the importance of the notion of *historically-specific social form* as the distinguishing mark of Marx's *Capital*.

Rubin, therefore, was at pains to shed light on value as a specifically-capitalist *social* phenomenon. But, according to one of the main arguments of his *Essays*, the same should be concluded about abstract labour, which constitutes value's substance. In this sense, Rubin (1972, 135) considered that it was quite simply impossible to see abstract labour as a sheer physiological expenditure of labour-power and, at the same time, grasp value as historically-specific. At this point, his train of thought thus confronted what Patrick Murray (2016, 431) eloquently called 'Rubin's dilemma': there was an inescapable need to choose between a 'generally applicable concept of abstract labor', as more or less explicitly 'Ricardian' readings of Marx's works did, and the idea that abstract labour must be a 'labor of a specific social sort'.

At first sight, the terms of this dilemma seem to make sense. However, as Rubin (1972, 135–36) himself acknowledged, the textual evidence from Marx's works was hard to reconcile with his own position concerning this dilemma. Despite these exegetical difficulties, the reception of his work among Marxists during the 1970s uncritically accepted the terms of 'Rubin's dilemma'. Thus, among the overwhelming majority of those who attempted to break with the Ricardian 'received wisdom', most intellectual efforts were geared towards clarifying the precise sense in which abstract labour should be grasped as a purely social and historically-specific phenomenon.[2]

In broad outline, it is possible to discern three different ways in which the specialised literature has addressed this *problematique*. The first one is direct heir to the solution proposed by Rubin himself, albeit read in a one-sided 'circulationist' manner (Eldred and Hanlon 1981; Heinrich 2021; Reuten 1993). Succinctly put, this perspective argues that it is the act of exchange of the products of labour for money, i.e. the effective relation that they establish *after* the production process has been completed, which equalises use-values as values and, through this mediation, transforms private, concrete individual labours into social, abstract and socially necessary labours. In other words, abstract labour is conceived of as concrete labour equalised through the act of exchange between ordinary commodities and money. As we shall see in more detail in a subsequent section, one of the problems of this view is that Marx's analysis of the substance of value clearly shows that it is not abstract labour in act, but its objectification that is specifically represented as the value of the commodity. This might seem an obvious point, but it is clearly overlooked by this train of thought, which claims that value and abstract labour are not presupposed by the actual exchange of commodities but come into being through it. And this is something rather difficult given that the exchange of commodities does not entail any process of material production. And the latter is the only moment at which (productive) labour properly can exist; at least according to any meaningful definition of it. At the moment of exchange, abstract labour is already materialised so it can hardly come into existence then.

A second current that views abstract labour as a capitalist social form grounds its historical specificity in the alienated character that it takes once the production process is subsumed under the command of capital. Abstract labour is thus grasped as wage-labour which, by virtue of its subsumption under capital, results in a socially-imposed abstraction 'from the lived experience of the workers' (De Angelis 1995, 110) or 'from concrete human circumstances and purposes' (Bonefeld 2010, 262). It is, in other words, 'alienated labour' (Kliman 2011, 182). As pointed out elsewhere, some versions of this approach (cf. De Angelis 1995 in particular) thus quite simply fail to distinguish between wage-labour under the command of capital and any other mode of human labour subjected to exploitation. Paradoxically, the alleged historical specificity of abstract labour fades away. In effect, the abstraction from the life experience, desires and purposes of the producers is also applicable to the social determinations of the slave and serf (Kicillof and Starosta 2007a). More importantly, all the versions of this general argument share the same formal-methodological problem in the structure of their reasoning. More concretely, if the explanation of value requires the category of abstract labour and, in turn, the latter entails the unfolding of the capital-form as its own prerequisite, it is unclear how self-valorising value (i.e. capital) can be explained *without* the prior account of the determination of value.

Lastly, a third stream adds some complexity to the matter. These authors re-introduce the notion of a 'physiological' sense in which all labours are equal without relinquishing the idea of abstract labour as the historically-specific form which is value-producing. The common argumentative strategy usually revolves around the doubling of abstract labour into more than one 'category' or, alternatively, assigning it diverse meanings depending on the context of the Marxian exposition at stake. Thus, the transhistorical determination of abstract labour as a physiological expenditure of labour-power is usually maintained for the initial analytical stage in which it is discovered as the content behind the exchange relation, whilst it is depicted as a historically-specific social form when it is considered as the substance of fetishised social relations. For instance, some scholars distinguish between abstract labour as the material remainder resulting from the abstraction of the particular useful character of labour, and 'social abstract labour' (Robles Báez 2014, 295) or 'practically abstract labour' (Murray 2016, 124) when referring to a form of social mediation, i.e. as socially-validated individual labour by means of the exchange between commodities and money. 'Physiological' abstract labour is thereby conceived of as an 'analytical category' or 'dialectical presupposition' which is conceptually necessary to present the 'truly social' historically-specific concept of abstract labour (Murray 2016, 125; Robles Báez 2014, 295).

Now, our main reservation against this latter perspective is that it essentially replicates Rubin's own solution (1972, 139), which consisted of the introduction of a varied spectrum of 'intermediate categories' to refer to the *different social roles* of the *same* real phenomenon. The only difference would be that these authors would preserve the *term* abstract labour as a differently-predicated constant in the different categories, which seemingly allows them to remain more faithful to the letter of Marx's texts and avoid 'Rubin's dilemma'. However, as shall be discussed in the following chapter, this merely is a formal way of sidestepping that thorny issue, which eventually and inevitably ends up relapsing into problematic circulationist tropes concerning the determination of value. On the other hand, we think that the extrinsic introduction of categories in the systematic-dialectical investigation has serious methodological consequences for the critique of political economy (Kicillof and Starosta 2007b). For, in stopping short 'at the fixed determinacy and its distinctness *vis-à-vis* other determinacies' (Hegel 1999, 125), science becomes impotent to comprehend the movement of contradiction – the inner negativity – that constitutes the immanent unity between the different determinations of real forms. In other words, the way to avoid the abstract identity between material and social determinations of value-producing labour characteristic of Ricardian interpretations is not to replace it with an abstract difference.

The Wertkritik's idiosyncratic solution to 'Rubin's dilemma'

Against this backdrop, the approach of the so-called German *Wertkritik* stands out for developing a reading of Marx which perhaps offers the sharpest contemporary challenge to Rubin's dilemma. It is worth starting with the assessment of the work of Robert Kurz, who was a leading figure of this current, and who developed an in-depth critical discussion of the nature of abstract labour in his book entitled *The Substance of Capital*. In our view, one of the main merits of this approach is that it resolutely acknowledges 'the material character of the substance of abstract labour' as a sheer 'expenditure of human brain, nerves, muscles' (Kurz 2016, 29). However, unlike the naturalism of Ricardian readings, Kurz emphatically insists that value is a *purely social fetishised* '*representation*' of this 'actual physical substance' which, 'however, has nothing physical about it' (31). Therefore, one could argue that by distinguishing between the materiality of abstract labour as physiological expenditure of human corporeality and its purely social representation as value, Kurz manages to break with the unmediated connection between abstract labour and value which underpinned Rubin's dilemma. Unfortunately, this is not the implication that he draws from his own analysis. Instead, still caught in the web of Rubin's dilemma, he goes to great lengths to find a way to maintain that abstract labour must still be a capitalist phenomenon after all.

Kurz (2016, 24) starts by throwing into relief that only in capitalist society does human productive activity involve the practical abstraction from the concrete form of labour and its reduction to a physiological expenditure of energy. Whilst that phenomenon of a 'real abstraction' might be true enough, it should be noted that it alone has no way of turning the physical 'combustion of energy' into an exclusively capitalist phenomenon. However, instead of acknowledging this at this point, Kurz actually raises the stakes and postulates that 'labour' as such, and not simply abstract labour, as other Marxists would have it, is a historically-specific social form.

His argument is that since 'in the name of the social form determination (value) […] the concrete activity, cabinet making, here counts practically as "labour", as mere expression of the expenditure of human energy as such' (Kurz 2016, 87–88), the capitalist social life process not only entails the 'practical doubling' of the concrete and abstract materiality of human productive activity into a two-fold social character; in addition, 'the former is subordinated to the latter' (88), so that concrete labour becomes 'the mere form of appearance of abstract labour' (89). On the other hand, Kurz's argument goes on, this abstraction from the useful properties of the different productive activities means that abstraction is made from all other social purposes other than the setting into motion of material production as such. Labour, which is rendered by Kurz as just 'one kind' of human activity among others, is thereby conceived of as 'a space "disembedded" from the total life process' (89); it becomes 'the self-mediation of substance and consequently the end in itself and self-aggregation in the value-form' (21). Seen in this light, Kurz concludes, 'strictly speaking the term "abstract labour" is a logical pleonasm (like "black darkness") since the attribute is already contained in the concept; "labour" being already an abstraction' (27). As a matter of fact, Kurz even submits that only under these social circumstances does the 'conceptual nominal abstraction "labour" as the concept of a social universality' make any rational 'sense at tall' (88). In this manner, Kurz considers that he has successfully resolved 'Rubin's dilemma': grasped as a socially 'autonomised' and self-mediating productive 'combustion of human energy', abstract labour results *both* a physical substance *and* a historically-specific social form.

Now, it seems to us that this latter broader ramification of Kurz's argument, which resignifies 'labour' as such as historically-specific, is highly polemic and begs many questions about the determination of the human species-being and the content which gives unity to its historical development (Starosta 2022). Nevertheless, Kurz (2016, 24) does not probe deeper into the question and just dismisses it through the hyperbolic remark that Marx remained 'stuck in the Protestant-Enlightenment ontology of labor'. On the other hand, one could still consider that his essential point comes down to the narrower question of the formal imputation of historical specificity to abstract labour, which does not have major consequences. In effect, at a more substantive level, Kurz in the end would be, albeit in a rather convoluted way, just correctly acknowledging that value is the purely social representation of the physiological expenditure of labour-power.

Yet, the conception of 'labour' as an exclusively capitalist phenomenon is not harmless for the comprehension of value as a reified social relation. First and foremost, this means that Kurz misses the whole point of the social form of value adopted by the products of labour, which is to be a historical mode taken by the organisation of the immanent material unity of individual labours as differentiated organs of social labour. Consequently, he fails *explicitly* to ask, at the appropriate 'level of abstraction', the question that political economy 'never once asked', namely: 'why this content has assumed that particular form, that is to say, why labour is expressed value' (Marx 1976a, 174). On this score, Kurz (2016, 31) does not go beyond indicating that the value representation is explained by the fact that abstract labour 'cannot really be separated from the concrete form' and 'cannot be literally contained in the objects'. But this still begs the question of precisely *why* the objectification of the abstract character of labour needs a distinctive representation as a social property of the product. Whilst Marx responds to this question in the first chapter of *Capital*, Kurz locates his answer only at the systematic stage of the capital-form, when he explicitly addresses the *foundation* of the social process of scission of abstract labour from its irreducible material inseparability from concrete labour. More specifically, the socially-determined separation of the materiality of abstract labour occurs because 'for the "automatic subject" of the process of self-expanding value it is completely inessential whether trousers or hand-grenades are manufactured; all that is essential is that *bodily human combustion processes* (expenditure of energy) take place' (30). As should be evident against the backdrop of the previous section, insofar as it needs the capital-form (i.e. self-valorising *value*) to explain the social constitution of value itself, this is a fundamentally circular argument.

This weakness carries over into Kurz's discussion of the *magnitude* of value. Specifically, the implication is that the *quantum* of value which is objectified in each individual commodity is not seen as determined at the effective moment of the privately-performed material exertion of abstract labour, albeit socially counting only as an aliquot part of the total labour-power of society (Marx 1976a, 129). Instead, he submits that it is circulation that 'measures the socially valid quantity of this already present value-objectivity' and 'establishes how large the value-objectivity is', although it 'does not manufacture it' (Kurz 2016, 198). What is more, so much does Kurz reduce the necessity of value to a merely 'instrumental' need for a socially-separable representation of a materially-inseparable substance, that he maintains that use-values acquire the social form of value even if their *salto mortale* as commodities 'fails to take place', with 'the value character of the commodity' manifested 'in its senseless disposal instead of consumption' (78). However, as we discuss both in the next section and the following chapter, insofar as what is at stake in value-production is the organisation of the immanent *social* character of individual labour, the products of labour cannot have value if they are not *social* use-values. Yet their 'senseless disposal' only proves that they were not determined as such from the very outset of the respective cycle of social metabolism, i.e. at the time of their production.

Now, some of these problematic issues with Kurz's approach have been somehow addressed in the more systematic and rigorous Marx exegesis of 'second-generation' *Wertkritik* author Anselm Jappe. Particularly in his commentary on chapter 1 of *Capital*, Jappe (2003) seemingly parts company with Kurz in his explicit acknowledgement that Marx's argument hangs on the fact that the primordial general social process that all societies need to undertake is the organisation of individual labours as materially interdependent organs of social labour. Consequently, this dovetails with Jappe's recognition that the historicity of capitalism derives from the specific form in which it resolves this process (50ff.). What is more, unlike Kurz, Jappe does throw into relief that this specificity is defined by the private character of social labour. Thus, he states that Marx is very clear that 'the fact […] that labour is represented in value, does not constitute an original datum' but is 'a consequence of a determinate mode of socialisation […] based on the labour of separate private producers' (58).

Unfortunately, this reworking of the *Wertkritik* perspective is still not profound enough to avoid lapsing into Rubin's dilemma. Thus, after recognising abstract labour as the 'sheer expenditure of labour-time, without regard to the specific form of its expenditure' (Jappe 2003, 31), just a few paragraphs later Jappe states that there is nothing ‘material and concrete’ about abstract labour; just like value, it is ‘purely social’ (33). Moreover, the reason for this latter conclusion is exactly the same as the one adduced by Rubin, namely, that grasping abstract labour as a ‘purely physiological fact’ would lead, as happened with Smith and Ricardo, to think that labour is value-producing ‘independently of all social determination and existing in all societies’ (43). In the end, it turns out that ‘the particularity of commodity production’ no longer resides in private labour but ‘in the fact that […] a non-specific, transhistorical property is transformed into a historically-specific mode of sociality’ (54–55). Jappe, therefore, ends up confounding the essential defining feature of capitalist society, i.e. the private organisation of the general unity of social labour, with its necessary yet *mediating consequence*: the abstraction from the concrete useful form in which that private expenditure of social labour has been realised.

At this juncture, and probably as a result of his inability successfully to tackle Rubin’s dilemma, Jappe (2003, 119) cannot help falling back into Kurz’s flawed solution, whereby ‘“labour” itself is a historical phenomenon’ insofar as a ‘definite mode of activity is – spatially and temporally – torn asunder from the rest of the full field of human activities’. The initial acknowledgement that the primordial social process in any society consists of the organisation of the allocation of the total available labour-power into its different concrete forms is suddenly put to one side. And such an idea, which Jappe concedes is Marx’s own, is now relegated to yet another expression of the latter’s lapse into an ‘ontology of labour’ resulting from his ‘bourgeois legacy’ (121). Instead, Jappe argues that ‘only in capitalist society […] does labour exist in an autonomous and separate sphere *vis-à-vis* other activities’ and therefore becomes ‘its own principle of organisation’ and ‘the reason to be of society’, whereas in prior societies material production was ‘at the service of a given social order’ (126).

As argued elsewhere concerning a similar argument by Postone (Starosta 2022), the very choice of terms in these formulations (‘at the service of a social order’, ‘[dis]embeddedness’, ‘social context’) betrays the irreducible externality in the relation that these authors end up positing between labouring ‘activities’, which become consequently represented as a sheer material process lacking in immanent social content and, on the other side, ‘overt social relations’, whose inner purpose and general unity (i.e. their ‘*raison d’être*’) is never *positively* spelt out (they are only *negatively* defined as not grounded in labour), but which are nonetheless said to impose, from such exteriority, their (self-grounded?) meaning and significance to labouring activities and their products.

Abstract labour and value in chapter 1 of Capital

The initial unearthing of abstract labour and value through the analysis of the commodity

In the opening paragraph of *Capital*, Marx (1976a, 125) starts with the immediate observation of the form in which social wealth appears ‘*in societies in which* *the capitalist mode of production prevails*', namely, an 'immense collection of commodities' (emphasis added), the *individual* commodity being its elementary form. Thus, out of that heap of commodities, Marx picks out a *singular* 'specimen' in order to proceed to its investigation, the first phase of which consists in its *dialectical analysis* (Starosta 2016, chapter 4). As Marx himself succinctly puts it in his retrospective methodological remarks in the 1864 manuscript published as 'Results of the Immediate Process of Production':

> We begin with the commodity, with this specific social form of the product – for it is the foundation and premise of capitalist production. We take the *individual* product in our hand and analyse the formal determinants that it contains as a commodity and which stamp it as a commodity.
>
> (Marx 1976b, 1059, emphasis added)

Note that in this passage Marx is very emphatic that his analysis begins, quite literally, with the individual commodity as such. What is more, although the English rendition as 'individual commodity' is not entirely eloquent in this regard, the German original, 'einzelne Product' (Marx 1988, 30), much more clearly denotes that at stake here is not just the singular but also the *isolated* commodity. Of course, it goes without saying that this is an 'isolated product' which is not an abstract mental or logical construct. On the contrary, it is the 'simplest economic concretum' (Marx 1975, 199) that has been abstracted, for the purpose of setting the dialectical exposition into motion, from the whole 'collection of commodities'. The latter certainly is the *yet-to-be-posited* real presupposition of the systematic-dialectical presentation. However, as immediate object of the investigation, both that initial collection of commodities and, more specifically, the multiplicity of their mutual exchange relations, will be 'bracketed out' until the unfolding of the 'formal determinants that it contains as a commodity and which stamp it as a commodity', necessarily drives us to turn our attention to those exchange relations among commodities.

Insofar as the immediate object of the exposition is neither the formal logical analysis of an abstract exchange relation (cf. Böhm-Bawerk 1949) nor the underlying structure of an all-round system of commodity exchange (cf. Rubin 1972, 85), it follows that in the opening pages of chapter 1, Marx is not searching for a common property shared by the world of commodities as the cause of their respective exchange ratios. Rather, his dialectical analysis consists of the search for the specific determination defining the potentiality (i.e. the power, aptitude or capacity) of the commodity as a historical form of social wealth. This potentiality Marx first 'discovers' by observing the use-value of the isolated single commodity that constituted the starting point of the presentation, which shows that in capitalist societies such a sensuous corporeal materiality acts as carrier of a second, *historically-specific* attribute of objects of utility; which, in this initial encounter and only provisionally when, 'flirting with Hegel', one could say that the exposition is still in the commodity's 'sphere of simple immediacy', Marx refers to as *exchange-value*.[3]

Here a problem might arise because Marx does not explicitly say what that second attribute of the commodity consists of. He just names it ('exchange-value') and then directly proceeds to its analysis. We think that the reason for this is that the meaning of that attribute was self-evident in the term itself against the backdrop of its everyday usage at that time.[4] The fact that commodities have 'exchange-value' simply means that they have the *power of exchangeability*, that is, *the aptitude to be transformed into any different use-value without the mediation of any material transformation in its bodily existence* (Iñigo Carrera 2021, 14). It is this wholly *non-natural* power that gives commodities such a mystical character, which nevertheless *all* strands of political economy naturalise, and whose genesis and constitution the *critique* of political economy thereby needs to explain. What immediately follows in Marx's exposition is, then, the *dialectical analysis* of this purely social power of exchangeability of commodities. That is, Marx proceeds to answer what is the source of this specific potentiality intrinsic to the commodity, i.e. what is the more abstract determination or content appearing in the concrete form of the power of exchangeability.

As happens with every phenomenon, the first thing Marx encounters when facing the exchangeability of the commodity is its *immediate manifestation* – the quantitative relation 'in which use-values of one kind exchange for use-values of another' (Marx 1976a, 126). It is just at this point, *once the power of exchangeability had already been found in the 'isolated single commodity'*, that the exposition *circumstantially* turns to examine the exchange relation between commodities. Now, the first step in the analysis of exchangeability is the separation of the *content and form* of that specific attribute of the commodity, this being the only way in which the scientific inquiry can pierce through the concrete form in which a more abstract form (hence a determined *content*) outwardly appears. This analytic distinction between form and content reveals that the multiple *particular* exchange relations that a commodity establishes with other commodities are actually expressions of something else that inheres *in each commodity*, and which entails an identical *qualitative* potentiality of *general* exchangeability in a certain *magnitude*. As a matter of fact, Marx shows that under the real practical premise of universal commodity exchange which constitutes the object of his study, even the examination of a singular exchange relation suffices to throw into relief the necessity for the existence of an identical quality in each commodity as its very condition of possibility. In this sense, Marx is not, as Böhm-Bawerk (1949, 68ff.) would have it, trying *logically to prove the existence of a common property among commodities*, but *the commodity itself*, by virtue of the immediately observable 'empirical fact' that it establishes an exchange relation which can be represented in an equation, shows that it *has* a 'common quality' *immanent* in it.

Once outer form of expression and inner content of the attribute of general exchangeability have been distinguished, Marx continues with the analysis of the latter, which consists, in turn, in separating that power of general exchangeability from the more abstract form whose realised potentiality it carries within itself as its 'other'. In other words, he proceeds to the identification of the *content* of the property of exchangeability, '*independent of their exchange-relationship or from* *the form, in which they appear as exchange-values*' (Marx 1976c, 9, emphasis added). Crucially, at this juncture, Marx thereby leaves the analysis of the exchange relation momentarily behind and shifts his focus back onto the commodity.

There are various tricky aspects in this phase of Marx's presentation, which might have contributed to much of the confusion among his readers. First, although by that point of the argument he has already shown that the common 'something' is the form of general exchangeability, he does not actually *name* it until separating it, in turn, from its own content or substance.[5] That intrinsic social power of general exchangeability which is manifested in exchange-value, and whose material substance consists of the objectification of the abstract character of labour, is called by Marx *value* (1976a, 128).

Second, and consequently, this way of structuring the exposition may have proven insufficiently emphatic in bringing out the distinction between the *physiological materiality* of *objectified abstract labour* and the *purely social objectivity* of its *representation* as the value of the product. This could have facilitated both the naturalistic reduction of the social form of representation to its substance by 'Ricardian' readings and, conversely, the 'dematerialisation' of abstract labour by 'formalistic' overreactions.

Third, this is further compounded by another salient feature of Marx's presentational architecture, which very strictly demarcates the *analysis of the commodity* in section 1 from the *analysis of the labour that produces commodities* in section 2. Thus, in the former, the qualitative differences between the various concrete labours are analytically transcended simply by *leaving aside* or *abstracting from* 'the determinate quality of productive activity' (Marx 1976a, 134). In other words, in the consideration of *objectified* labour, the substance of value is disclosed as 'human labour-power expended *without regard to the form of its expenditure*' (128, emphasis added), i.e. as a '*negative* residue'. But the characteristics of that 'which remains' upon the abstraction from use-value and concrete labour are not yet *explicitly* spelt out by Marx at that initial stage. By contrast, in the analysis of commodity-producing labour, hence of labour as *activity*, the exposition progresses to the discovery of the underlying *positive material quality* of the substance of value as 'an expenditure of human labour-power, in a *physiological* sense' (137, emphasis added).[6] This *two-stage* train of reasoning about abstract labour in Marx's presentation is usually overlooked in most readings, thereby allowing for a spurious contrast between an initial definition allegedly based on a 'socially-forced' abstraction from the irreducibly concrete materiality of labour and a subsequent allegedly 'naturalistic' definition as simple 'productive expenditure of energy'. As we have seen, this is one of the textual sources of the so-called 'Rubin's dilemma'.

Finally, Marx structures his search for the content of value as social form in terms of the *objectified substance* which is represented as the *property* of exchangeability. Thus, at this stage of the analysis, Marx does not bring to the fore the 'value-forming' *activity* of this substance but tends to focus more narrowly on its *result*. In other words, he throws into relief its existence as already 'crystallised' or 'congealed' in the product of labour. As Marx (1976a, 142) himself later puts it in section 3, at this juncture he is facing labour only in a 'coagulated state', in 'objectified form', rather than in 'fluid state'. This presentational strategy might have the merit of rigorously sticking to the analysis of the social form of the *product of labour* without unduly and prematurely overreaching into the analysis of *human labour* as such. However, as Iñigo Carrera (2021, 119ff.) points out, this somehow comes at the cost of not placing sufficient emphasis, from the very initial stages of the systematic exposition of the value, that the latter can only come into existence by being *posited* by some prior *action*. More generally, as Iñigo Carrera goes on, from a materialist perspective all existing attributes or powers of things (be them natural or social) can only come to be as a result of some *action* which bestowed those properties upon the respective objects.

In the specific case of the commodity, insofar as, on the one hand, its social power of exchangeability is *materially* and *individually* borne by its 'natural form' as a use-value and, on the other, Marx makes a brief but undisputable case for discarding the action of purely natural forces as the substance of value, this necessarily implies that *the human action that posits value in the commodity must also be the same action that posits its use-value* (Kicillof and Starosta 2007b, 19). On the other hand, it is also evident that the action positing value and use-value cannot be *exactly* the same action, since they are two different attributes of the commodity. Were it the same action in all and every respect, it would not be possible for it to posit the *two* different attributes whose *unity* constitutes the commodity as a historical form of social wealth. Marx (1976a, 132) thus solved this apparent paradox by being 'the first to point out and examine critically' that 'the labour contained in commodities' is an action which embodies two different aspects or, as Marx puts it, possesses a two-fold character, namely: concrete and abstract labour.[7]

This last point might seem yet another minutia. However, it involves significant implications for the matters under discussion in this chapter. For, to begin with, this clashes head-on with the claim found in much of the literature that abstract labour, as the substance of value, comes into being through the exchange relation. More specifically, this latter perspective renders inexplicable the *two-fold* representation of the labour objectified in the commodity, which, as stated above, can only be posited by two facets of the same human action that produces the materiality of the use-value which acts as a carrier of its value. And insofar as exchange is not the human action that intervenes in the material constitution of the use-value of the commodity, it cannot possibly be the action that posits its value either (Iñigo Carrera 2021, 17; Kicillof and Starosta 2007b, 19).

On the other hand, the fact that concrete and abstract labour must be distinct *aspects* of the same human productive action, whilst the latter cannot just 'cease to be' a material phenomenon which, as all actions (whether human or not), involves a process of transformation of energy, necessarily implies that abstract labour must be an irreducible determination of human labour's 'physical' or 'natural' existence (Iñigo Carrera 2021, 123). In other words, *ex definitione*, the abstraction from the useful character of labour cannot lead to the sheer wholesale negation of all materiality of human transformative activity upon nature, thus leaving only (non-human) nature as material residue and turning the abstract character of labour into a 'purely social reality' as, for instance, Bonefeld (2010, 264) would have it. *Strictu sensu*, the latter view does not even grasp the mutual relationship between concrete and abstract labour as that between distinct *aspects* of human productive action, namely: its universality (*Allgemeinheit*) and its particularity (*Besonderheit*), as Marx (1976a, 169–70) puts it in the section on commodity-fetishism, when contrasting their respective roles in the organisation of the social character of labour in modern society *vis-à-vis* pre-capitalist modes of production. Instead, perspectives such as Bonefeld's conceives of it as an externally-related opposition between concrete labour as material content and abstract labour as its purely social form of existence.[8]

In fact, we have seen that this is one of the strongest points of Kurz's (2016, 210) acute critique of both Rubin and Heinrich (which he even extends to Postone). More concretely, that extremely strict demarcation between the substance of value and 'the natural basis of human life' overlooks that 'the metabolism with nature [...] is in no way external to social forms' (210). Consequently, it ends up caught in antinomic forms of thought that tear asunder the immanent unity between the materiality of human life and its sociality into externally-related 'worlds', 'as if physical human existence had nothing at all to do with their sociality and history, as if it were not *this physical, bodily existence itself that is located in a social and historical form*' (195). Crucially, as argued elsewhere (Kicillof and Starosta 2007b), despite its attempt to avoid ahistorical views of abstract labour and value, this self-proclaimed 'anti-substantialist' train of thought ends up glossing over the very contradictory unity between materiality and social form which is specific to capitalist society, whereby the sheer physiological productive expenditure of human energy acts as the vehicle for the organisation of the unity of social labour. In other words, in this society the immediate process of production of material wealth becomes, at the same time, the production of the objectified capacity effectively to partake in the intrinsically social metabolic process of human beings, namely, value.[9]

As a matter of fact, this is exactly what Marx (1976a, 164), in the fourth section of chapter 1, singles out as *the* phenomenon which gives the product of labour an 'enigmatic character [...] as soon as it assumes the form of a commodity', and on which his *critique* of political economy attempts to cast light (unlike its naturalisation by political economy). He does not state that the source of the commodity's mysticism lies in the fact that the irreducibly concrete materiality of labour becomes coercively-subsumed under, and is thereby extrinsically transformed into, the 'purely social reality' of abstract labour. Instead, after reiterating for the 'nth' time that

> however varied the useful kinds of labour, or productive activities, it is a *physiological fact* that they are functions of the human organism, and that each such function, whatever may be its nature or its form, is essentially the expenditure of human brain, nerves, muscles and sense organs,
>
> (164, emphasis added)

he then continues in the next paragraph that what is *mysterious* is that such *plain and obvious* material 'equality of the kinds of human labour takes on a physical form in the equal objectivity of the products of labour as values' (164).

Thus, we think that the analytic search for the specific determinations of the commodity is evidently not fully achieved with the discovery of abstract labour as the substance of value. Quite to the contrary, that very specificity seemed to have slipped through Marx's fingers. In effect, although he found the specific attribute of the commodity in its value, when he moved to account for its substance, he ended up with a substance which bears no specifically-capitalist character, namely: (objectified) abstract labour. Thus far, then, this stage of the analytic process does *not* show *why* this physiological materiality, once objectified in the product, takes on the value-form. It does not even tell us *what* is the historical form of social labour which is determined as value-producing. It *only* tells us *what* is the material content of that which in capitalist society is *socially* represented as the 'value' of the product. This is the reason why Marx still carries on with the analytic search for the '*formal determinants* that it contains as a commodity and which stamp it as a commodity'.[10]

From the analysis of the dual character of labour to the synthetic unfolding of the content and form of the value-determinations

This leads Marx's dialectical analysis to give closer scrutiny to the labour that produces commodities. As any attentive reader could tell, the analytic process *continues* and only in the section on the dual character of labour does Marx finally find the historically-specific form of social labour that produces commodities and, hence, value. In effect, Marx observes that the individual commodity he is analysing is only one among many within a totality of different commodities. But the same follows for the particular labours that underlie the varied use-values taking the commodity-form. In other words, Marx (1976c, 12–13) points out that generalised commodity production presupposes the existence of an extended social division of labour and that the latter, as the 'totality of varying deployments of useful labour', is an 'eternal necessity of nature for the sake of mediating the material interchange between man and nature (i.e. human life)'. On the other hand, this analysis also makes clear that the reverse relationship does not hold, that is, the division of labour must not necessarily take the social form of the production of commodities. The formal determination of the commodity must, therefore, spring from the specific social form taken by the organisation of the division of labour in our present-day society. The commodity, Marx (1976a, 132) eventually concludes, is the objectification 'of mutually independent *acts of labour*, performed in isolation' (emphasis added). In other words, it is the fact of being the 'labour of private individuals who work independently of each other' (165), or *private and independent labour* (hereafter, *private labour* for short) that Marx's analysis singles out as the specifically-capitalist mode of existence of human productive activity, and which makes it value-producing.

Marx's analysis of commodity-producing labour then turns to revisit its other facet as abstract labour, which he had already discovered as the objectified substance of the commodity's value. However, as already anticipated, this further examination of abstract labour as '*active* substance' allows Marx (1976a, 134–35) to probe deeper into its own determination beyond being just a 'remainder', and he unequivocally concludes that it is a 'productive expenditure of human brains, muscles, nerves, hands etc.' that comprise 'the *simple* labour-power […] possessed *in his bodily organism* by every ordinary man' (emphasis added).[11] The *positive* material 'quality of being human labour' as such (136) now comes to light as that which forms the substance of value.

Yet this in no way means a lapse into the *abstract naturalism* of Classical political economy. Thus, commodities certainly 'possess an objective character as values *only in so far* as they are all expressions of an identical social substance, human labour' (Marx 1976a, 138, emphasis added), but *not simply because of that*. That 'transhistorical' aspect of labour becomes such source of the purely social property of general exchangeability of its product by virtue of the *historically-specific* determination which the analysis of the two-fold character of the labour also brought out, namely: the private form of social labour. In sum, value becomes finally laid bared as the social representation of the abstract character of socially necessary, privately-undertaken labour objectified in the product.

The analysis of commodity-producing labour thus completes the answer to the question about the nature and source of the commodity's specificity that had set the dialectical investigation into motion. However, the latter is far from coming to an end. Now we know *what* makes the product of labour take the form of a commodity. But this still begs another fundamental question which remains unanswered: *why* when social labour is organised through privately-undertaken individual labours, the abstract physiological materiality of labour, insofar as it is expended in socially-useful fashion and in the socially necessary labour-time, must 'congeal' in the social form of the value-objectivity of its product? As argued at greater length elsewhere (Starosta 2016, chapter 4), the analytical progress of the systematic-dialectical method proves incapable of offering an answer. At this juncture, Marx's dialectical exposition thereby reverses course and moves, in section 3, to the *synthetic ideal reproduction* of the unity between content and form of the determinations so far discovered, i.e. to the necessary expression of that more abstract determination in its more concrete form of existence.

More specifically, this synthetic movement consists in unfolding the actualisation of the attribute of exchangeability (i.e. value), which is the potentiality that was analytically uncovered as immanent in the commodity. From then on, the commodity is no longer analytically grasped in its exteriority as an 'inert' or 'lifeless' object, and the exposition starts to follow its self-movement as the subject of the development of those determinations previously discovered through analysis.

It is as an outcome of this synthetic movement of ideal reproduction of this formal mediation, when seen in unity with its *qualitative content*, that the answer to the questions which the analytic stage was impotent fully to provide is given. In other words, the development of the necessary expression of value as exchange-value *also* reveals, albeit in the mode of an inverted reflection (Marx 1976a, 150), *why* the objectification of the abstract character of privately-performed labour takes the social form of value or, to put it differently, why private labour is value-producing.[12] For reasons space, we cannot flesh out in any detail all the intricacies and complexity of a systematic exposition which Marx firstly unfolds, rigorously sticking to 'the inner life of the subject matter', in 'the language of commodities'.[13] Here we would only like to make a few remarks drawing inspiration from a very rich passage from the first edition in which Marx succinctly brings together the results of his dialectical development of the genesis of the general equivalent-form, which, we think, concisely sums up the underlying necessity for both the constitution of the value-objectivity and its outer expression through the polar doubling of the commodity-form into 'ordinary' commodities and money (see Marx 1976c, 31–32). What is the conclusion that Marx infers from this exposition of the inner structure of the 'exchange-value or the form of value'?

First and foremost, that 'all use-values are commodities only because they are *products of mutually independent private labours,* private labours, which however materially depend upon one another as particular, even though autonomized members of the naturally system of *division of labour*' (Marx 1976c, 31, translation modified based on Ehrbar 2010b, 105). Marx thus reiterates and leaves no doubt that the simplest specific form-determination of labour in capitalism that determines its products as commodities is not being abstract labour but private labour. Moreover, although this social process certainly takes the inverted or alienated form of an impersonal 'system of objective compulsion' over individuals, its essential content is not being a 'relation of subjugation' (Kurz 2016, 206), but a historical mode of existence of the organisation of the *immanent* social character of individual productive activities as qualitatively differentiated organs of the social division of labour.

Second, the expression of value, now grasped in unity with the content that constitutes it, reveals that the distinguishing mark of this mode of organisation of the social life process lies in the fact that the producers do not *consciously or directly* relate, as individual organs of social labour, at the moment of the allocation and expenditure of the labour-power that they embody in a particular concrete form. Instead, the social character of their activity, the fact that they are producing use-values for others, can only *be expressed* in a socially-recognisable form only in an *indirect* (or mediated) manner, namely, through the exchange of its products as commodities. Hence, the form of value brings to view, albeit 'in a roundabout way' (Marx 1976a, 142), that it is the product of labour that acts as the immediate bearer of the capacity to effectuate the general social relation that gives material unity to the individual organs of social labour.

However, the product of labour can only act as such reified mediator not simply by embodying determinate material properties which make it apt for the satisfaction of the human needs of another individual. The universal scope and impersonal nature of the exchange relation have shown that the products of private labour can only validate their determination as social use-values by firstly proving that they are *universally exchangeable entities*, i.e. they can only affirm their natural potentiality as an object of utility 'for people other than its possessor' by being 'set into *social* rapport' (Marx 1976c, 28). In other words, it is by being determined as 'bearers of value' that socially-useful products of private labour can fulfil that mediating social role – 'although this property never *shows through*' (Marx 1976a, 143, emphasis added) in the sensuous corporeal materiality of each isolated individual product, which is why it must be outwardly manifested in the use-value of a particular product of private labour which the world of commodities jointly designate as general equivalent.

Still, this contradiction in the product of labour is but an objectified, mediated expression of the fundamental one which is intrinsic to commodity-producing labour itself. Although at stake is the general organisation of the material interdependence among the different individual useful labours as particular organs of the social division of labour, the formal autonomy between the private producers means that the social character of their activity cannot be *consciously* posited *before* production takes place and *based on the concrete character of their labour*. They do not produce for themselves but for others with whom they have no overt nexus of direct dependence, so that 'it is indifferent just whose needs the commodity's useful properties relate it to' (Marx 1976c, 28). In other words, they cannot organise the productive exertion of the individual labour-power that they embody with a view to satisfy the needs of a 'definite other', but can only do it for a 'general, yet undefined other'. Similarly regarding the private producer's multifarious 'participation in the world of products, in consumption' (Marx 1973, 172), which also materially depends on the products of labour of those 'general others'. Yet, 'mediation must, of course, take place' (171) for the process of human metabolism with nature to secure its continued reproduction. Thus, this contradiction can 'find room to move' by mediating the material unity between social production and consumption on the basis of the only remaining social nexus among private producers, which is that each of them embodies an aliquot part of the total labour-power of society, i.e. the capacity to perform labour 'sans phrase' (Iñigo Carrera 2021, 44). The private labour of the commodity-producer thereby must acquire an additional, historically-specific social character: its common 'universality' as sheer physiological expenditure of labour-power, i.e. the abstract character of human labour's materiality, must act, once 'coagulated' in its product, as the vehicle for the establishment of the general unity of the human life process (Marx 1976a, 166). Important conclusions can be inferred from this.

To begin with, this remains a *material* process, which, however, takes place behind the backs of individuals. This is the reason why it must be ideally *reflected* in their heads, through a 'primordial and hence unconsciously instinctive operation of their brain' (Marx 1976c, 36), in the form of the 'purely social' value-objectivity of the products of labour (Marx 1976a, 166). In this sense, Kurz's (2016, 105) emphatic characterisation of the materiality of abstract labour as the 'combustion of human energy', in contradistinction to its *fetishistic social representation* as an attribute of its product, is entirely on the mark. However, and here we part company with the conclusions that he draws, this does not turn abstract labour into a specifically-capitalist social form. In other words, it is not *being* abstract labour, 'which is what all human labours – whatever their content and their mode of operation – actually *are*' (Marx 1976c, 32), but *socially relating* by means of that physiological determination, which constitutes the specific social form of value-producing labour. As Marx continues in the passage just quoted, 'in each social form of labour, the labours of different individuals are related to one another as human labours too, but in this case this *relating itself* counts as the *specifically social form* of the labours' (32).

Furthermore, Kurz and Jappe are on the right track when they insist on the historical specificity of the antithetical 'social doubling' of the 'universal' (abstract) and 'particular' (concrete) materiality of human labour. However, in one-sidedly fixating on this significant and undeniable aspect of capitalist social relations, the authors from the so-called *Wertkritik* either simply gloss over (Kurz) or merely pay lip service to (Jappe), the *private character of social labour*. The latter is what constitutes the *differentia specifica* of this mode of production and which, at any rate, constitutes the *foundation* of such 'practical sundering' of the 'combustion of human energy' from the concrete forms in which it is expended. By contrast, Kurz and Jappe end up elevating a *derivative phenomenon* into the *essential ground* of the capitalistically-determined social life process.

To conclude, abstract labour as such cannot be simply identified with value-producing labour, which is what virtually all the literature takes for granted as a self-evident fact. Instead, as argued in this chapter through a close reading of Marx's argument in the first chapter of *Capital*, value-producing labour is *privately-performed (socially necessary) abstract labour*. Rubin's dilemma crops up as soon as one fails to grasp all these determinations *in their underlying unity* and treats each of these 'moments' as a one-sided self-sufficient 'category'. At bottom, we think that there is a unifying thread which underlies the inability to escape Rubin's dilemma in most of the contemporary literature on the value-form, namely: a problematic conception of the place of the material determinations of human life in the critique of political economy, which eventually fails to grasp the immanent contradictory unity between materiality and social form that forms the movement which Marx expounds in the whole of *Capital*.

Notes

1 For a good introductory overview to the main contemporary controversies, see Pitts (2021).

2 Saito's reading (2017, 102ff; Sasaki and Saito 2015), drawing on the so-called Kuruma school (Kuruma 2017; Otani 2018), represents a notable exception to this overriding Marxist consensus. In a nutshell, Saito takes issue with Rubin's dilemma because it 'says no more than "value-creating-labor creates value"' which is 'is merely a circular argument' (Saito 2017, 108). Instead, and similarly to the perspective adopted in this chapter, he maintains that the defining characteristic of commodity-producing labour is its private character, whilst abstract labour represents a transhistorical phenomenon (104). However, in contrast to our approach, Saito considers that private labour 'does not become a part of the entire social labor at the moment of labor's execution', but only through a 'detour' by means of the 'exchange between products' (106). As we shall see in the next chapter, this kind of argument is riddled with problems to explain the specificity of value-producing labour. Furthermore, Saito postulates that abstract labour plays 'a social role […] in any society' (108), an argument which, for reasons fleshed out below, is also incorrect. For its part, Carchedi (2011) is another author who acknowledges that abstract labour is a 'transhistorical' physiological expenditure of labour-power, whilst conceiving of value as a social form specific to capitalism. However, in line with other interpretations that we critically examine below, he ends up referring to a 'specifically capitalist abstract labour' which can only be explained at the level of abstraction of the capital-form (152).

3 Later, when recapitulating the content and form of the formal determinations of the commodity in their unity, Marx (1976a, 152) looks back and corrects his initial ill-chosen terminology, making clear that what he called 'exchange-value' in those opening passages, was actually and already what he would some paragraphs later call, more rigorously and precisely, 'value': 'When, at the beginning of this chapter, we said in the customary manner that a commodity is both a use-value and an exchange-value, this was, strictly speaking, wrong. A commodity is a use-value or object of utility, and a "value"'.

4 As attested by Marx's reference to his initial use of the term exchange-value 'in the customary manner' quoted in the previous footnote.

5 In the first edition of *Capital*, Marx (1976c, 9) does name *value* before proceeding to the analytical search for its content. Heinrich (2021, 58) correctly notes this.

6 In section 3, Marx (1976a, 159) comments on how the specific polar structure of the expression of value in the use-value of the general equivalent brings out, in its correspondingly mystified and inverted fashion, this positive quality of abstract labour *vis-à-vis* its mere 'negative presentation' as a residue.

7 As Ehrbar (2010a, 1312) perceptively notes in his *Annotations to Karl Marx's 'Capital'*, this *implicit* line of reasoning in Marx's analysis of the commodity is *explicitly* fleshed out much later in Chapter 8, when explaining the way in which the *same productive action* of the worker *simultaneously* adds new value and preserves the old value materialised in the means of production. As Marx (1976a, 307) puts it, 'it is plain that this two-fold nature of the result can be explained only by the two-fold nature of his labour'.

8 As Ehrbar (2010a, 136) clarifies, the German word that Marx introduces to refer to the 'two-fold character' of commodities and commodity-producing labour is '*Zwieschlächtiges*', which more literally means 'two-edged' (as in the expression 'two-edged sword'). This translation as 'edge' (or alternatively, 'moment', Ehrbar suggests) makes it even plainer that the relationship between concrete and abstract labour is not between content and form.

9 Marx's reference to abstract labour as *social* substance is not, as Heinrich believes, irrefutable proof that 'it does not express any natural qualities' and that it thereby is 'something purely *socially* determined' (Heinrich 2021, 66). To the contrary, it is the perfect terminological synthesis of the contradictory unity between physiological materiality ('substance') and historically-specific role ('social') of the productive expenditure of human labour-power 'sans phrase' in capitalist society.

10 Note that had abstract labour as such constituted the specificity of value-positing human action, Marx's analytical search would have come to an end.

11 The question of simple and complex labour will be discussed in great depth in Chapter 4.

12 See Marx's (1976a, 142) discussion in the subsection on 'The content of the relative form of value' for the argument that these are not two different questions but a two-fold question with the same answer.

13 But see Starosta (2016, chapters 4 and 5). The next two chapters of this book shall also partly cover this ground.

2 The determinations of value as historically-specific social form

Part II: production and circulation

Introduction

As we have seen in the previous chapter, in order to avoid lapsing into 'asocial' representations of the commodity-form of the product of labour, a great deal of contemporary readings of *Capital* are at pains to throw into relief the historical character of economic categories, abstract labour primordially among them. As we have also noted, within this rather broad new consensus, some scholars have taken an additional idiosyncratic step in their attempt to part company with Ricardian conceptions. More specifically, what we have referred to as 'circulationist' strands of argument can also be regarded as a deliberate theoretical strategy to keep the chances of Ricardian retrogressions at bay.

Although the 'foundational' ideas can be traced back to the pioneering contribution of Rubin (1972) in the 1920s, which has constituted the main intellectual source for the circulationist revival since the 1980s (Eldred and Hanlon 1981; Reuten and Williams 1989), this approach has been quite vehemently revamped in more recent times in the influential work of the German scholar Michael Heinrich (2012; 2021).[1] Let us, therefore, examine the specific way in which he makes his case for the circulationist reading of Marx's investigation of value in his commentaries to Marx's *Capital*.[2]

The contemporary 'circulationist' (over)reaction to the naturalistic reading of *Capital*: the case of Michael Heinrich

Heinrich's discussion starts out with the correct observation that the gist of Marx's argument in the first chapter of *Capital* does not simply boil down to the claim that 'value is an objectification of human labor' and 'the magnitude of value depends upon the "socially necessary labor-time"' (Heinrich 2012, 44). If this were the case, Heinrich continues, 'then Marx's value theory would not have gone very far beyond classical political economy' (44). Instead, he further notes, at stake in Marx's investigation of the determinations of value as a historically-specific social form is, 'under the conditions of commodity production, […] how privately expended labor becomes a component part of the total labor of society' (47). In this sense, 'value theory […] should explain the specific social character of commodity-producing labor' (47).

DOI: 10.4324/9781003201939-3

So far so good. However, Heinrich then elaborates on this process of fetishised mediation in the establishment of the unity of social labour through the exchange of the products of labour as commodities. And when he moves to conceptualise the connection between privately-undertaken individual labours and the general unity of social labour, his formulation shows the three paradigmatic hallmarks of the circulationist approach: the products of private labour are deemed to enter the exchange relation exclusively as use-values, and it is the latter phase of the social metabolic process which is seen as transforming the former into 'bearers of value'. Moreover, this train of thought continues, through the mediation of this transformation of the product of labour, a further two-fold transformation takes place: the producer's private labour is converted into social labour and the concrete character of labour is transformed into abstract labour. In other words, it is the equalisation of heterogeneous use-values on the market, i.e. the effective relation that the products of labour establish *after* the production process has been completed, which converts them into actual commodities and, *retroactively*, transforms private, concrete individual labours into social, abstract and socially necessary labours.

Thus, Heinrich (2012, 49) states that when the reproduction of society as a 'particular totality' is mediated by commodity-producing labour, '*during the act of exchange*, an abstraction is made from the use value of commodities, and the commodities are equated *as values*'. In other words, from the undisputable fact that the 'value-objectivity is "purely social"', Heinrich (2021, 95) draws the far from self-evident conclusion that 'it cannot be a single thing's property' so that 'commodities have value-objectivity only in the social relation of one commodity to another'. In this sense, as he furthermore bluntly puts it, 'prior to and outside of this relation', the products of private labour 'are mere use values: they are on the way to becoming commodities, but far from being commodities' (95). In turn, this idea that 'value […] first exists in exchange' (Heinrich 2012, 53) is grounded in Heinrich's conceptualisation of abstract labour as the social substance of value. In effect, the latter is not seen as a material aspect of human productive activity in general but as 'a relation of social validation existing only in exchange […] the substance of value, and thus the value-objectivity, is something only obtained by things when they are set into relation with one another in exchange' (52–53).

In brief, the reified determination of the products of private labour as bearers of value, i.e. of the power of general exchangeability, is not considered as a *presupposition constituted in the direct process of production*, which, as an *entirely social yet immanent* aptitude, capacity or potentiality, therefore, *allows* privately-produced use-values to establish the exchange relation. As a matter of fact, he even submits that the very idea that value is 'a property of an individual commodity' can only be a 'substantialist illusion' of 'traditional (i.e. naturalistic or Ricardian) Marxism', and so is the view that the magnitude of value is 'determined, independent of the exchange process, by the quantity of socially necessary labor-time expended in the *production* of the commodity' (Heinrich 2012, 54).

But if this is so, how is it possible for different commodities to establish an exchange relation given that, as Bonefeld (2010, 265), drawing on Heinrich himself, perceptively notes: 'exchange cannot take place without equality, and equality not without commensurability'? Put differently, Heinrich's line of reasoning begs the question of how heterogeneous use-values can become formally identical and, *on that basis*, be even able to relate as equivalents in exchange in the first place.[3] Certainly not by virtue of their qualitative and quantitative 'physiological' or material identity as 'coagulations' of the socially necessary abstract labour expended in their production, since, according to Heinrich, the existence of that social substance of value is explained by the act of exchange itself.[4] Thus, as argued elsewhere (Kicillof and Starosta 2011), this perspective ends up caught in a fallaciously circular train of thought: commodities become equal because they exchange but they can only exchange because they are already equal. Alternatively, it cannot but lapse into a tautological explanation which attempts to ground a determinate phenomenon through the sheer enunciation of the form of that phenomenon itself (Hegel 1999, 458ff.). As Heinrich (2021, 115) explicitly puts it, 'the product of private labor […] obtains a *value-form* through exchange and thus becomes interchangeable', i.e. products of labour are exchangeable (they are bearers of value) because they exchange.

In light of these issues with the circulationist approach, it might be worth at this stage throwing into relief the key qualitative matter at stake which underpins the whole question of the respective roles of production and circulation in the social determinations of abstract labour and value, namely: the establishment of the material and social unity of privately-undertaken individual labours. In this sense, the circulationist stance on abstract labour and value is but a further consequence of a view which is ultimately grounded in a representation of private labour as having absolutely no objectively-determined social character before exchange. Only at the latter moment of the social metabolic process is private labour said to *become* part of the total labour of society. More specifically in the case of Heinrich, he remarks that in a commodity-producing society, 'the particular labor activities *are not yet social when they are carried out*' (2021, 152, emphasis added). In other words, at the time of its performance in the direct production process, individual labour '*is not yet* a component of the aggregate labor of society' (154–55, emphasis added). Instead, he further claims, 'such labor is private labor, and its socialization first occurs *retroactively,* through the exchange of products' (154–55).

Note that in Heinrich's formulation, the exchange process is not seen as retrospectively *confirming* whether or not the *original* allocation of the private producer's individual labour *had been undertaken in a socially-useful fashion*, i.e. whether it was determined (or not) as an effective element of the material unity of the social division of labour *at the moment of its actual expenditure and objectification in the process of production*. Instead, Heinrich characterises the market 'sanction' as *determining ex-nihilo* the inclusion (or exclusion) of already objectified private individual productive activities in a general social division of labour whose qualitative articulation is deemed to *come into being* at the very moment of exchange. In other words, the objective material and social interdependency of privately-undertaken individual labours is not considered as the *premise* which the exchange process validates 'post-factum' in a socially overt form, but as the latter's pure *result*.

Hence, Heinrich's characterisation of private labour deprives the direct production process of its *objective immanent social character*. In his account, the essential social determination becomes displaced to the exchange process and, similarly to Rubin's pioneering circulationist arguments, it is conceived of as only (logically) later 'projected' onto the production process by means of the subjective purpose and ideal estimates of the commodity producer (Heinrich 2012, 55; 2021, 155–56). As argued in connection to the early Rubin's circulationist leanings elsewhere (Kicillof and Starosta 2007), this can only result in an *external* relation between the value-form and the materiality of the direct production process. The latter ends up represented as a merely material process of production of use-values, which is *extrinsically* 'shaped' by the historically-specific form of the *circulation* of social wealth, which becomes inverted into the social foundation of the human metabolic process as a whole.

At this point, and in order to place our critical assessment of the shortcomings of circulationism on clearer and firmer ground, we think it is fundamental to probe deeper into the meaning of the private and independent form taken by social labour in commodity production. So, before turning to the examination of other contemporary alternatives to circulationist value-form theory, let us take a momentary detour and briefly examine the matter more closely.

The immanent social character of human labour and its private form[5]

Whatever its specific social form, all act of labour has a two-fold character which is *immanent in its materiality*: individual and social (Starosta 2022). On the one hand, it is the human individual's productive expenditure of their corporeal powers with a view to appropriating and transforming external nature into a means for human life. On the other hand, those individually borne productive powers can only be constituted socially, that is, they can only develop as the outcome of the productive action of other individuals (who, for instance, have participated in the production of the use-values whose consumption resulted in the productive attributes borne by the former individual's labour-power). Moreover, and crucially for the matter under discussion, the individual labourer produces use-values not solely for their own consumption, but to satisfy the needs of others, that is, *social* use-values (Marx 1976a, 131). Although an irreducibly individual human action, 'as soon as men start to work for each other in any way' (164) labour therefore *always* has an *intrinsically* social character as well.

The private and independent form taken by the organisation and establishment of the unity of social labour does not *do away* or *abstractly negate* this social determination of individual *living* labour *in act or in motion*, i.e. *as it exists in the direct process of production*. What happens in a commodity-producing society is that this immanent general social character of individual labours is not carried as a *conscious determination* by the working subject. Thus, as a private and independent human being, the producer is incapable of consciously recognising that their productive action possesses social determinations that transcend the immediacy of its singularity. Consequently, when organising the expenditure of the labour-power that they embody, the human individual must project or transpose – hence confront – those individually borne social powers as external to their individuality and existing as the objective attribute of the product: the social property of exchangeability or the value-form.

Note, however, that this 'primordial and hence unconsciously instinctive operation of their brain', which reduces the 'material thing to the abstraction, *value*' (Marx 1976b, 36), is but the fetishised form in which the private producer resolves the organisation of their individual action as part of the unity of the social metabolic process of human beings. And insofar as the latter has its starting point and ground in the act of production (Marx 1973, 99), the *objectivity* of value must be necessarily *constituted* already at that opening phase of each cycle of human life activity. Indeed, it is only by virtue of being already determined as exchangeable objects or 'bearers of value' as they emerge from the direct labour process, that materially heterogeneous products of labour can even enter into relationships as 'equivalents' in exchange, designate one of them as the money-commodity to sensuously express their suprasensible 'social soul' and, in this roundabout manner, *manifest indirectly* the human subject's *immanent determination* as an individual organ of social labour. As in every act of social accreditation, at stake in the exchange relation is the *confirmation* of whether an 'intrinsic' qualitative attribute in need of 'recognition' *was present or not before the act of accreditation itself*.[6]

As Kliman (2011, 180–81) comments in his case for a production-centred yet non-naturalistic approach to value,[7] this idea that 'commodities are values when they are produced' is usually regarded by circulationist value-form theorists as an asocial perspective for which, in a Ricardian manner, 'the transformation of commodities into money appears to be something merely formal, which does not penetrate deeply into the very essence of capitalist production' (Marx 1989a, 325). In other words, if the social character of private labour were fully established in the act of production, the circulationist objection goes, then the qualitative and quantitative articulation of the system of division of labour would seemingly lose its characteristic haphazard and spontaneous nature (Marx 1976a, 202). Whilst this certainly is a fair objection to Ricardian-Marxist approaches to the subject that dominated the literature until about 40 or 50 years ago, it is far from being the general case that it is a necessary consequence of a production-centred approach to the value-form. Let us see why.

As remarked above, the specificity of commodity production derives from the fact that the *immanent* social character of individual labours is not carried as a *conscious determination* by private producers. In other words, what remains to be established in circulation, upon completion of a privately-undertaken production process, is not the *positing* or *constitution* of those social determinations (i.e. their coming into objective existence), but their explicit outer *expression* and *accreditation* in a socially-recognisable and generally-valid manner. However, it does not follow from this that the determination of the socially-useful character of private labours is conceived of as 'guaranteed', thereby downplaying the indirect form of social relations of production in capitalism. But the 'success or failure' at privately producing *social* use-values (hence commodities), i.e. to effectively establish a social relation, is *determined* at the very moment of production, although it can only *manifest indirectly* through the connection established by the products of labour in the exchange process. Thus, in the case of a socially-useless expenditure of private labour, its product will eventually prove *not* to have been a 'bearer of value', and hence a commodity, already at the point of production; albeit that condition would only be *revealed a posteriori* in and through the exchange relation. By contrast, if the private material expenditure of individual labour was done in a socially-useful concrete form (and let us add, was expended in the socially necessary labour-time), the resulting product will successfully and effectively be able to relate as 'exchangeable' in the circulation process (i.e. establish a value-relation) for identical materialisations of the abstract character of socially necessary private labours. Of course, in the mode of an expression 'in consciousness' through *ideal* quantities of the general equivalent, both socially-useful and useless products of private labour will indistinctly *appear* in circulation as bearers of the price-form stuck on a tag. However, only the former, as actual commodities or exchangeable objects proper, will be able to *realise* that merely ideal price, i.e. undertake the '*salto mortale*' through a successful sale.

Finally, there is an additional implication of this alternative view on the role of production and circulation in the determination of value, which concerns the 'genesis of the money-form' and its synthetic expression in the three peculiarities of the equivalent-form. In *Capital*, Marx presents the three peculiarities of the equivalent as the *inverted form* in which the (relative) commodities *outwardly reflect*, hence resolve and develop, their *inner* (but 'hidden') contradictory character as use-values and values, i.e. as materialisations of the unity of concrete and private labour, and abstract and social labour. As already discussed, this is a social determination which commodities acquire as they emerge from the direct process of production, and which constitutes the very *condition of possibility* for the establishment of the exchange relation. This is also true of the commodity serving as equivalent, which can only express in its own natural body the value of the other commodities in the relative pole, only because it is an identical private materialisation of abstract socially necessary labour. However, as with any commodity, the one acting as equivalent simultaneously is 'always the product of some specific useful and concrete labour' (Marx 1976a, 150). And also 'like all other commodity-producing labour, it is the labour of private individuals' (150). What is peculiar about the equivalent commodity is that its use-value and the concrete private labour that produces it, become socially recognised, or 'count' (as Marx puts it in the quote below), as the direct embodiment of their respective opposites: value and abstract social labour. Yet Marx is adamant that the commodity acting as equivalent can 'count' as such immediate representative of abstract social labour within the exchange relation, because it already has such property objectified in it (142–43). Conversely, the rest of the *useful* private products of socially necessary abstract labour, *even though they do possess those properties prior to and independently of the exchange relation*, cannot *directly appear* as such bearers of those material and social determinations in their 'coarsely sensuous objectivity as physical objects' (138). That is why they must necessarily reflect them externally in the body of the equivalent.

In sum, the necessary development of the equivalent-form, and hence of the money-form, is the result of the exchange relation between socially-useful products of private labour *already determined as equivalents* as a result of the immanent social determinations of the respective privately-undertaken direct production processes. The relative expression of value in the concrete form of exchange-value only *polarises* the (in)capacity *directly* to *manifest* that determination in the respective bodily existence of commodities and money. But it does not *engender* the determination itself. This immanent unity between the qualitative *content of value* and its *necessary form of expression* in the mode of exchange-value, which is contained in the *value-relation* between two commodities, is succinctly summarised by Marx in *Capital* towards the end of the subsection on 'The Simple, Isolated or Accidental Form of Value', where he fleshes out the results of the latter subsection:

> The internal opposition between use-value and value, hidden within the commodity, is therefore represented on the surface by an external opposition, i.e. by a relation between two commodities such that the one commodity, whose own value is supposed to be expressed, counts directly only as a use-value, whereas the other commodity, in which that value is to be expressed, counts directly only as exchange-value.
>
> (Marx 1976a, 153)

Note that in that passage above, Marx unequivocally states that the 'internal opposition between use-value and value' is '*hidden* within the commodity', *in the singular*. The '*relation* between two commodities', *in the plural*, which is *premised on* that opposition hidden in the *individual commodity*, represents the latter in an externally visible manner. Against the backdrop of the prior discussion, this can only mean that the *constitution* of the *inner* opposition, which takes place in the process of production and becomes objectified in each product of private labour (on condition that it is expended in a socially-useful concrete form and in the socially necessary labour-time), pre-exists its outer *expression* in and through the exchange relation. As Marx puts it at the opening passages of section 3 of chapter 1 on 'The Value-From, or Exchange-Value', what 'remains impossible' is not for the *single* isolated commodity that he is analysing to *have* a dual nature as 'an object of utility' and a 'bearer of value', but for an 'observer' to *grasp* (i.e. consciously recognise) its 'objectivity as value' in the coarsely sensuous objectivity as a physical object.

However, in his commentary, Heinrich glosses over this change of angle on the question, which is reflected in Marx's precise choice of words ('to have' versus 'to be grasped'), i.e. the transition from the individual commodity's *possession* of value to the *form of appearance* or *manifestation* of that intrinsic property 'in the social relation between commodity and commodity', and thereby wrongly concludes that 'as a specific product, an *individual* commodity is simply the outcome of a particular useful and individual labor activity' and 'can only become an expression of *equal human* labor through exchange, when confronting other commodities' (Heinrich 2021, 94). But insofar as value acquires its fully-developed shape as exchange-value through the money-form, i.e. through the 'social interweaving' of the function of general equivalent with the natural form of a specific commodity (historically, gold), Heinrich's train of thought implies that the objective existence of value and abstract social labour can only result from the exchange of products for money. Yet gold can monopolise the role of direct material incarnation of abstract socially necessary private labour in opposition to 'ordinary' commodities (i.e. become the general equivalent), for being such bearer of value itself prior to assuming its social determination as money. But if the existence of value (and abstract social labour) results from the exchange of products for money, the existence of the latter is rendered inexplicable. In brief, the circularity in the circulationist account of the social power of general exchangeability of the products of private labour translates into the inability to explain the development of money.

Now, many of these pitfalls of the circulationist perspective have not remained unnoticed by other contemporary Marxist scholars who, as much as the former, have also attempted to move beyond the old 'traditional Marxist' or 'Ricardian' orthodoxy that had dominated the readings of *Capital* until the 1980s by insisting on the historicity of the determination of value as a reified social form. In light of our own production-centred, yet wholly social, alternative formulation of the connection between production, exchange and value as just fleshed out, let us now turn to examine some of those other contemporary alternatives to the circulationist perspective.[8]

Critical remarks on some current attempts to overcome the pitfalls of the circulationist value-form approach

Contemporary production-centred approaches to value as a historically-specific social form

In a symposium on the 'Value-form paradigm' in the pages of the online journal *Critique of Political Economy*, Kliman (2011, 177) comments that the former approach's stress on the historical specificity of value must be applauded against the backdrop of 'Sraffian and other physicalist theories that dominated Marxian economics'. However, he critically notes that the 'typical value-form concept of value is unduly market centered' (178). More specifically, Kliman means by this that, according to the value-form paradigm, 'products acquire their values – and, *a fortiori,* their prices – if and when they are sold' (178). In other words, he rightly observes that in their valid attempt to avoid the naturalisation of the value-form, much of this literature lapses into untenable *circulationist* positions. Moreover, he also correctly notes that this is an unnecessary move and insists that it is possible to reconcile the idea of value as a historically-specific social form with a production-centred view of its determination.

Writing from a similar position to Kliman's, Posner and Gonzalez's contribution put forward important additional arguments against the circulationist reading, albeit with a more specific focus on the theorisation of abstract labour. In the first place, in agreement with the perspective that we upheld in the previous chapter of this book, they defend the view that abstract labour is a 'physiological' (hence transhistorical) determination of all human labour whilst its objectification as the value of the product is historically-specific. In other words, they claim that it is not abstract labour as such that is historically-specific, but its mediating role in the establishment of the social form of individual concrete labours (Posner and Gonzalez 2011, 205). Moreover, they correctly add that this social role of abstract labour is further mediated by 'the fact that this common equality of all human labor is transformed into an "objective characteristic" of the commodities themselves […] socio-natural properties of these things […] i.e. as its value' (205).

In the second place, they point to an issue that also resembles a critical remark on circulationism that we made in the previous chapter. Thus, they seem to draw the correct implication that unless we acknowledge the 'physiological' *materiality* of abstract labour, there is no way in which we can claim, as we have seen Marx emphatically does, that abstract labour is not a *kind or type* of labour, but an *aspect* or *facet* of living labour. More concretely, they acutely observe that, at the phase of exchange, labour, as human productive activity, has *ceased to exist* (Posner and Gonzalez 2011, 206–8). As they bluntly conclude: 'It would therefore be absurd to speak of value as a substance produced by the laboring human subject, since it would not be *produced* at all' (207).

In brief, both Kliman's and Posner and Gonzalez's contributions aim at disputing the claim that 'a concept in which [products of labour] become values when they are produced, before and irrespective of sale, is transhistorical' (Kliman 2011, 179). More specifically in the case of Kliman, the key to his case is that the idea of value as labour 'embodied' (or 'materialised' or 'congealed') in the process of production, is not necessarily Ricardian, as most value-form theorists believe. According to Kliman, the reason for this is that for Marx, and unlike for Ricardo, the 'embodiment' of labour in the commodity does not simply mean that labour has been expended in its production, but that, upon its expenditure, it has taken the fetishistic form of a 'phantom-like objectivity'; it has become a purely 'social substance' (182). To put it differently, Kliman argues that, as a matter of fact, the 'embodied labour' that constitutes the social substance of value is nothing else than what Marx (1992, 324) referred to in 1844 as "alienated labour", i.e. labour whose product not only constitutes its objectification but which 'confronts him [the worker] as hostile and alien'.

If we leave aside Kliman's rather debatable *semantic* claim that the term 'embodied labour' is *synonymous* with 'alienated labour', we have no objection whatsoever to his *substantive* argument that value-positing labour entails, as a matter of fact, an alienated objectification of human productive subjectivity. Yet, there are a number of problematic issues in the rest of his otherwise commendable attempt at making a case for a historically-specific *and* production-centred view of the determination of value. As Murray perceptively observes in relation to Posner and Gonzalez (but the thrust of the argument is equally applicable to Kliman), these contributions correctly grasp the 'definition' of commodity-fetishism (the 'what'), i.e. that physiological abstract labour takes the objectified form of a purely social property of the product of labour, namely: value. However, they fail to offer an actual *explanation* of the social determinations which turn the general materiality of the expenditure of human labour-power into the substance of an objectified form of social mediation (i.e. the 'why'). Albeit with recourse to what we see as a problematic categorial demarcation between 'physiological' and 'practically' abstract labour (see Chapter 1 of this book), Murray (2016, 434) pins down quite lucidly and precisely the pitfalls of his opponents in the debate: they do not indicate 'what specific feature of capitalist production is responsible […] for transforming abstract labour into a supersensible property of the commodity'.

This leads us to a further shortcoming of both Kliman's and Posner and Gonzalez's production-centred account of value as a historically-specific social form. In reality, Murray's perceptive critique on the grounds that they leave the social constitution of the value-objectivity unexplained is only partially on point. Strictly speaking, they do lay down an explanation; but the problem is that they locate it at the wrong systematic 'level of abstraction'. In other words, their explanation is missing from where it actually belongs, which is at the level of the simplest determination of the capitalist mode of production, i.e. the commodity-form. Instead, both Kliman (2011, 183–85; McGlone and Kliman 2004, 143ff.) and Posner and Gonzalez (2011, 209–10) consider that the social process which turns the sheer physiological materiality of the expenditure of abstract labour into the 'socially real' substance of an objectified social relation (i.e. value) is the subsumption of labour to an alienated purpose, namely: capital's incessant drive to self-valorisation. However, as already argued in the previous chapter, this is a fallacious train of through, which just presupposes what needs to be explained. In effect, insofar as its general determination is to be self-valorising *value*, the systematic development of capital as a social form evidently needs the prior unfolding of the more abstract determinations of the social constitution of value.

Now, there seems to be an underlying reason for these scholars' denial that the ground of the social determination of labour as value-producing resides at the level of the commodity-form. More specifically, they seem to equate this more abstract determination of social existence simply with 'the market' as a 'mode of commerce', whilst the 'mode of production' is seen as solely acquiring determination once we reach the level of the capital-form (Kliman 2011, 185). But, as Murray himself stresses in his critique of Arthur's treatment of value as a contentless 'pure form' until reaching the level of capital, the commodity-form is not simply a mode of *circulation* of social wealth (even if, as we shall see below, Murray fails correctly to grasp the connection between the immanent social character of production and the process of exchange). The commodity-form of the product of labour is, above all, the simplest determination of the organisation of the general social unity of capitalist *production*.

That is why Kliman ends up missing the mark with two wrong-headed criticisms of the value-form paradigm. On the one hand, he submits that value-form scholars confuse the defining distinctive feature of capitalism, which is not to be a 'market monetary economy' but the existence of labour-power as a commodity.

However, as Murray (2016, 437–38) correctly notes in his rejoinder, it is a methodological error to abstractly oppose the generalised production and circulation of commodities, which furthermore develops the necessity of the money-form, and the capitalist mode of production. For, from a systematic-dialectical perspective, the generalised commodity-form is nothing else than the simplest or most abstract determination of the capitalist mode of production.

On the other hand, and building on this first critique, Kliman further submits that 'ironically, value-form theorists have tended to regard relations of production as transhistorical – just like Ricardo and the Ricardian-influenced authors they oppose. Thus the source of capitalism's distinctiveness is displaced to the sphere of exchange' (Kliman 2011, 184). This is incorrect and reflects Kliman's and Posner and Gonzalez's own inability to grasp the *simplest* source of capitalism's specificity as a mode of production and, more concretely, of its value-producing character. For the problem with value-form authors does not lie in their failure to see any historical specificity in the social organisation of the capitalist direct process of production. At least in the work of most sophisticated exponents of this paradigm, Murray among them (and, as we have seen, also Heinrich), they are very clear that this specificity lies in the *private* character of labour, a form-determination which neither Kliman nor Posner and Gonzalez even mention in their articles. The problem with *circulationist* value-form theorists, which we shall argue that Murray fails fully to overcome, is that they consider that the form of private labour entails the abstract or absolute negation of the immanent social character of individual living labour in the direct process of production.

In sum, both Kliman's and Posner and Gonzalez's contributions fail to offer a convincing case for a production-centred view of value as a historically-specific social form, thus paving the way for Murray's more nuanced reinstatement of circulationist leanings in the determination of value. We, therefore, now turn to the critical assessment of Murray's rejoinder and his 'co-constitutive' value-form theory.

Co-constitutive value-form theory

Those wrong-headed critiques of the value-form paradigm allow Murray (2016, 429) to structure his response by firstly pointing out that Kliman, Posner and Gonzalez have construed a strawman, since they do not distinguish between what he labels '*exchange-only* value form theory' and the 'co-constitutive view' that he endorses (427). The former is 'the extreme variant of value-form theory' that maintains that 'value and the magnitude of value are constituted exclusively in exchange', whilst the latter affirms that it is constituted in *both* production and circulation (427). Murray, therefore, is from the outset at pains to set his own approach apart from what he considers 'extreme' circulationist arguments, whilst still refusing to ground the determination of value solely in production. However, we shall see that although he does introduce some idiosyncratic nuances in his perspective, concerning the key issues at stake in this controversy his main substantive arguments do not significantly part company with those of Heinrich, whose pitfalls we have already indicated earlier on. In this sense, other than showing that, effectively, his approach shares the same circulationist take on the essential aspects of the social constitution of value as a social form (and is thus liable to the same objections that we raised against Heinrich), our discussion shall focus on the additional arguments that he brings up to justify his position.[9]

Thus, in virtually all his writings, Murray usually deliberately stresses the differences between the co-constitutive view, on the one hand, and both the extreme variant of 'exchange-only value-form theory' and 'labour embodied' approaches. The latter, allegedly Ricardian, position is that 'value is fully determined qualitatively and quantitatively in the sphere of production [and] is independent of money (indeed it is the independent variable that explains price, the dependent variable); money serves merely as a label for value and a convenient instrument for exchange' (Murray 2016, 454). Murray finds Eldred's 'extreme' value-form theory as the polar opposite of the Ricardian perspective, insofar as 'any mention of value prior to exchange is out, and any talk about value in terms other than monetary ones stops making sense' (454). In other words, Murray observes that the 'extreme variant of value-form theory affords us no basis for distinguishing between value and price' (430). Finally, he reads Marx's *Capital* as presenting the co-constitutive view that he endorses, according to which 'the qualitative and quantitative determination of value overlaps production and exchange (in keeping with the inseparability of production and exchange), so that value is "latent" in the sphere of production; it can be actualised only by being sold' (454). In a nutshell, both this notion of value as already *latent* in production and, concomitantly, a particular way of understanding its 'actualisation' through the *effective* sale of commodities, are, according to Murray, the distinctive substantive features that mark the co-constitutive approach. We shall return to the assessment of these ideas later. But, before that, let us first examine the extent to which, on the key issues that, in our view, ultimately define the stakes of the controversy between production-centred and circulationist approaches to value as a social form, Murray's perspective entails any significant difference from the essential circulationist elements that we have already discussed.

Against the backdrop of what he calls 'Rubin's dilemma', Murray does not simply reject the 'transhistorical' materiality of abstract labour as part of the value-determinations. Instead, he argues that 'abstract (physiological) labour' is one of the *two* concepts which are needed to explain the value-producing character of labour, the other one being what he names 'practically abstract labour' (Murray 2016, 124–29; 145–48; 431; 434). The key, Murray points out, resides in doing what, in his reading, Posner and Gonzalez fail to do, namely: to identify the simplest or most general historical determination of the 'specific social type of labour […] that is socially validated in practice as abstract in the physiological sense' (431–32). As already mentioned, Murray notes that this historical specificity which makes human labour commodity- or value-producing lies in the fact that it 'has an asocial sort of sociality; it is social, because it produces for others but, as *privately undertaken production*, it is not directly social' (285, emphasis added). In brief, value-producing labour is private labour (see also Murray 2016, 19; 28n98;

212; 213; 236; 270; 277). The problem, however, is the way in which Murray conceptualises the private character of labour.

More concretely, Murray (2016, 214) puts forward what he presents as 'a developmental conception' that 'encompasses production and exchange'. We take this to mean that the determination of the social character of private labour takes place *all along the two phases* that comprise the indirect unity between production and consumption. Thus, Murray suggests that the process begins in the sphere of production, where the expenditure of 'abstract labour in the "physiological" sense', which is '[t]he labour that congeals as value', firstly takes place (264). However, Murray warns against Ricardian readings, that sheer objectification of individual (privately-undertaken) abstract labour cannot yet be said to have produced value. Three additional conditions, pertaining to the social character of individual private labours and not simply to their natural materiality, must also be met (264–65). Firstly, it must be an 'hour of simple average labour', which is historically defined. Secondly, it must be 'socially necessary' in a technical sense, i.e. it must be expended under the *average* material conditions of production constituted across all the producers in the same branch. Murray subsequently suggests that if these two conditions which already involve 'social' dimensions, are met in the sphere of production, then the respective private expenditure of individual abstract labour initiates its 'transformation […] into socially valid labour' (212). In effect, the materiality of production sets 'limits' to the apparently arbitrary 'flow[s] of commodity exchange' (212).

Nevertheless, Murray is adamant that upon the completion of the act of production, the determination of the material expenditure of individual labour as an organic component of the total labour of society is not yet 'fully' established. According to his train of thought, up to this point, the determination of the socially-mediated material interdependency of individual private labour acquires, as it were, a preliminary or tentative character. Concomitantly, the constitution or formation of the value of the products of labour is only 'potential'; its presence in products 'prior to the sale' is only 'latent' (Murray 2016, 216). In order to 'finalise' the developmental process of conversion of individual productive activities into effective material components of the social division of labour, a third crucial condition must be met: they must be 'socially validated' both as 'abstract' and as 'socially necessary' labour, hence transformed into 'practically abstract', value-producing labour (287). But this, Murray states, 'occurs only in commodity circulation', so that 'demand "determines" value even before we get to the issue of the magnitude of value inasmuch as, without demand, there would be no substance of value to measure' (287). In sum, all this leads Murray to conclude that '*commodity exchange plays a co-constitutive role in the formation of value*' (216, emphasis added). The following quotation encapsulates, in a nutshell, Murray's 'developmental' and 'co-constitutive' conception of value:

> There is no value without the qualitative transformation of privately undertaken labour into socially valid labour, and that transformation cannot

> be completed in the sphere of production: to complete the circuit of value, commodities must be sold.
>
> (Murray 2016, 212)

As this passage should make eloquently clear, at least concerning the key matter at stake, i.e. the form taken by the organisation of the social character of individual labours, Murray (2016, 124) ends up relapsing into the classic tropes that make up the distinguishing mark of circulationism: value-producing labour is 'a definite historical type of labour, namely, the labour that produces commodities and is socially validated once those commodities are exchanged for the universal equivalent (money)'. True enough, Murray does allow for the presence of social circumstances that affect, already in the sphere of production, the historically-specific determination of privately-undertaken individual labour as value-producing, particularly with regards to the *quantitative* determination of value as constituted by 'socially necessary' and 'simple' labour. However, and crucially, Murray leaves no doubt that, with regards to the primordial *qualitative* question of the determination of the socially-useful character of privately-undertaken individual labour (i.e. that fact that 'it is social, because it produces for others' [285], but for 'unknown others' [213]), his stance remains unequivocally circulationist.

In effect, Murray (2016, 27) agrees with Posner and Gonzalez that 'human labour in the abstract is the substance of value where human labour is "practically abstract", that is, wherever human labour is socially validated as human labour in the abstract'. But, in his view, the *ground* for this specifically-capitalist 'way of recognising human labour' lies in '*commodity circulation, the buying and selling of commodities*', which 'is the social practice by which concrete labour is *transformed* into "practically abstract" labour' (433, emphasis added). In sum, despite Murray's laborious efforts to set his 'co-constitutive' value-form theory apart from the 'exchange-only' variant, it nonetheless shares with the latter the main tenets which are the source of its failure properly to grasp the inner unity of the content and form of the social character of private labour and, therefore, of the determination of value as a historically-specific social form.

First and foremost, Murray fails to grasp the social character of privately-undertaken labour as an *immanent* qualitative attribute, capacity or potentiality of *living labour in act*. Hence, although it is certainly true that in commodity-producing society 'there is no way to *tell* whether labour is "socially necessary" apart from the circulation of commodities' (Murray 2016, 287, emphasis added), it does not follow that the *determination* of individual private labours as *qualitatively* effective organs of the social division of labour (only/also) *takes place* in the exchange process (be it exclusively, as in 'extreme variants' of circulationism or in Murray's 'co-constitutive' role). Secondly, and concomitantly, Murray thereby seems to conflate the question of the social *constitution* of the *value-objectivity* as such, i.e. the *positing* of that qualitatively- and quantitatively-determined objective attribute of the socially-useful products of private labour which makes them 'bearers of value' or 'exchangeable things', with its necessary *outer mode* *of expression* in and through the exchange relation. Indeed, the very idea of 'co-constitution' places both production and exchange on *equal footing* as two distinct 'moments' through which the process of 'value-constitution' must undergo before the social property of exchangeability becomes qualitatively and quantitatively determined as an 'intrinsic' attribute or aptitude of the products of private labour. In this sense, although, unlike the 'exchange-only' value-form theory, Murray's 'co-constitutive' version might not entail what Freeman terms a sheer 'ontological collapse' between value and price (Murray 2016, 430), it does flatten out the 'stratified' difference between the *content* and *form* of the value-determinations. In other words, as Likitkijsomboon (1995) puts it in an early critique of Reuten and Williams' (1989) value-form theory, Murray also seems to end up collapsing different systematic levels of abstraction.

These two substantive issues dovetail with a couple of additional methodological remarks that Murray makes in his critique of 'production-centred' perspectives on value as a social form. The first one is that the latter tend to spurn the idea of real potentiality as a metaphysical hoax (Murray 2016, 428–29). More concretely, this would involve the rejection of the idea that 'the commodity's value is an intrinsic potential prior to its sale' (428), whose existence is 'merely "latent"' upon the completion of production and the 'determination of [which] [...] is impossible without measurement' in money (453).

Now, we think that here Murray conflates two clearly distinguishable issues, which are by no means mutually implied. Or rather, they are so only by virtue of Murray's particular stance on the meaning of 'real potentiality'. In fact, our own methodological perspective relies on this very notion without, however, leading to any circulationist leanings concerning the determination of value. More specifically, and as argued at greater length elsewhere (Caligaris and Starosta 2014; see also Chapter 3 in this book), dialectical thought ideally appropriates every form-determination of reality by facing it as embodying a qualitative potentiality, or determinacy, whose necessary realisation involves its self-development or self-transformation into another, more concrete form of existence. Moreover, it further grasps this first qualitative potentiality as the concrete form in which an even more abstract form-determination of reality realises its own qualitative potentiality, that is, its real necessity. Thus, dialectical thought proceeds by discovering as *immanent* in a particular concrete form the realised potentiality of another real form, which is abstract (or simpler) with respect to the first one, but concrete (or more complex) with respect to another form, of which it is the realised potentiality. In other words, dialectical thought grasps each form as the *affirmation through self-negation* of another, more abstract one (hence, as immanently carrying the necessity which drives them to self-movement). Important implications follow from this.

First and foremost, the more abstract form, which constitutes the *content* of a 'sensuously' immediate concrete *form* of reality is not, as Murray (2016, 440) puts it, simply the product of what Hume conceived of as a 'distinction of reason'. Thus posed, it would seem as if the difference between diverse 'aspects' or 'moments' of a certain phenomenon, whose immanent unity comprises the content and form of its determination, were a matter of mere 'subjective reflection' or 'mental abstraction', with no *objective* actuality other than that which is eventually acquired in its most immediate or 'sensuous' form of existence.[10] More concretely put, Murray appears to imply that the substance and magnitude of value, value as such and exchange-value, only acquire 'full' objective actuality in the form of price and, more precisely, in the effective market price at which the commodity is sold (440). In other words, the differentiated mode of existence between those actual aspects of reality would be solely a 'distinction of reason'. However, it seems to us that Murray is construing a false dichotomy between two equally one-sided views: the Humean reading of the connection between the different aspects of a phenomenon that he endorses, and the flawed procedure of what, following Hegel, he calls the 'understanding', which represents the manifold forms of reality as a universe of absolutely indifferent and 'ontologically' independent or self-subsistent entities.

In contradistinction to both views, we think that a properly dialectical perspective must come to grips with the full objectivity of the more abstract inner content of phenomena which, albeit necessarily *cognised by means of thought*, is as *objectively actual* as its outer manifestation in an immediately sensuous form. In other words, the self-negating development of the potentiality that defines an abstract form, into a more concrete form of existence, does not imply the passage from something still falling short of 'full' existence into 'proper' actuality. Rather it involves the self-transformation of the *mode* in which something already (and simultaneously) exists as both an actuality and a potentiality: the realised or actualised mode of existence of a more abstract or simpler potentiality, which consists precisely in a newly emerging more concrete or complex potentiality yet to be realised. In our view, by contrast, Murray's formulation tends to confound *real potentiality* with *real possibility*.[11]

Against this backdrop, one could argue that Murray conflates the idea of value as fully determinate potential or potentiality already constituted in production, which is necessarily activated, and thereby outwardly or sensuously expressed, in and through the exchange relation, with the very different notion that the product of private labour acquires in production the 'possibility of having value', with effective exchange or circulation finally resolving whether that possibility is realised or not, or in which magnitude it does so. But possibility is not the same as potentiality. More concretely, possibility is the form taken by necessity when a certain phenomenon embodies two different potentialities whose concurrent realisation is mutually exclusive, i.e. something that could or could not be (Hegel 1999, 546–47; Ng 2017; Iñigo Carrera 2013, 258ff.).

In this sense, we have already noted that value-positing is indeed a possibility for private labour and not a simple necessity, i.e. it is not 'guaranteed'. However, the resolution of that possibility already takes place at the moment of the organisation and execution of the immanent social character of private labour; it is a determination of *living labour in act*. Thus, the potentiality of the *material* expenditure of privately-undertaken abstract labour, *if* expended in a *socially-useful* fashion *and* with the *socially necessary* conditions of productivity and intensity, is actualised, *already in the sphere of production*, in the self-negated form of the purely social property of 'exchangeability' of the product, i.e. in the social form of value.

Upon the completion of privately-undertaken production, value is no longer a possibility but an already actual and determined potentiality. As we have also pointed out, what remains ‘latent’ in production is, therefore, not the qualitative and quantitative *constitution* of value, but the outer *expression or manifestation* in a sensuously (hence socially) recognisable form. In other words, the exchange relation serves as the vehicle for the expression of already-constituted yet ‘hidden’ value, in the self-negated form of exchange-value, i.e. in the shape of the direct exchangeability of a certain quantity of the use-value of the commodity acting as general equivalent or money.

Conclusion

As argued in the previous chapter, most contemporary readings of Marx tend to take at face value the terms in which Rubin approached his idiosyncratic understanding of chapter 1 of *Capital*. In a nutshell, this means accepting the argument that insofar as abstract labour is the substance of value, the only way to avoid the naturalisation of the latter is to see the former as a historically-specific phenomenon. In fact, so much has ‘Rubin’s dilemma’ become the virtually universal upheld view, that even contributions which go to great lengths to remain true to the unequivocal textual evidence that Marx saw abstract labour as a physiological productive expenditure of human corporeality, eventually succumb to the ‘categorical imperative’ to accept the claim that abstract labour must be, at least in some sense, a historically-specific social form.

By contrast, our own detailed reconstruction of Marx’s dialectical exposition of the value-determinations has shown that what defines commodity-producing labour is not its abstract character, but the private form taken by the organisation and execution of its immanent general social character. It is this latter historically-specific mode of existence of social labour that makes the physiological materiality of objectified abstract labour become socially represented in the reified, purely social form of value of its product. Seen in this alternative light, the first chapter of this book argued that Rubin’s dilemma and its uncritical contemporary reception prove to involve a spurious, unmediated connection between abstract labour and value.

Presumably partly by virtue of the influence of Rubin’s own attempted solution to the dilemma, and partly due to the seeming ‘safety’ against the risk of naturalisation of value associated with the old ‘Ricardian’ production-centred reading, a great deal of the contemporary literature tends to lean towards a ‘circulationist’ approach to value. In this chapter, we have taken issue with the different variants of this perspective, whether the more ‘extreme’ version or the more nuanced views which are at pains to give production its due place in the constitution of value as a social form. Moreover, we have critically discussed those production-centred alternatives which emphatically reject both the circulationist approach and the asocial stance of value characteristic of the old Ricardian reading. As we have seen, these latter views also fail to offer a rigorous production-centred and non-naturalistic grasp of the value-determinations.

Concerning ‘circulationism’, we have fundamentally argued that its main shortcoming is that it reduces the *social constitution* of the nexus between commodity producers to its necessary *form of manifestation* (hence *mediation*) in and through exchange. Privately-undertaken production is thus deprived of all *immanent* social character. On the other hand, we have seen that a sound overcoming of these limitations cannot revolve around the explanation of the social character of the immediate production process by its subsumption to capital, as most critics of circulationism end up doing. This would involve the fallacious procedure of necessitating the category of capital to account for the value-determinations. In opposition to both views, we have argued that the key to understanding value as both social and grounded in production resides in the recognition that at stake in value-positing is the ‘unconscious’ organisation of the determination of privately-undertaken labours as successfully integral individual organs of social labour; a fact which, albeit not ‘guaranteed’, becomes established in the sphere of production. Circulation only involves an *a posteriori* visible form of general social recognition of this process. It performs this necessary yet *mediating* role, through the inverted outward expression of the inner social property of exchangeability intrinsic to each individual socially-useful product of private labour, as the immediate social power of the general equivalent.

Appendix

Brief remarks on the magnitude of value

So far, we took issue with ‘circulationist’ arguments about the qualitative determination of value. In this appendix, we shall briefly examine those arguments but in relation to its quantitative determination. Succinctly put, the circulationist approach considers that the meaning of ‘socially necessary abstract labour-time’ (hereafter, SNALT) does not only refer to the material conditions of production but also to the effective solvent social need for a definite use-value. The magnitude of value would thereby not be fully determined until ‘effective demand’ eventually validates in circulation how much of that privately-undertaken production becomes part of the total social labour. In line with our previous argument, we shall also maintain that the circulationist approach confounds the content of the determination of the magnitude of value with its necessary concrete form of realisation. Our own argument will be structured through a reconstruction of Marx’s exposition.

In chapter 1 of *Capital*, Marx discusses the magnitude of value solely as a corollary of an investigation whose guiding thread lies in its qualitative determination. Consequently, his discussion does not go beyond a formal-analytical indication of the inner content of value’s quantitative determination and the elucidation of the necessity of its outward form of manifestation in the body of the equivalent. Specifically, Marx’s initial analysis of the exchange relation shows that value abstracts from all qualitative differences, so that its substance must also be qualitatively homogeneous. However, the analysis of the magnitude of the substance of value confronts us with two qualitative differences, namely: the productivity and intensity of labour. In this context, Marx simply makes the formal observation that the qualitatively-undifferentiated character of the substance of value implies that the singularity of each productive action, which involves individual material differences in the aforementioned two features of labour, must thereby socially count as identical to any other individual expenditure of human labour-power, i.e. as an aliquot part of the total labour-power of society or as an ‘average sample of its kind’ (Marx 1976a, 130).

This is all that Marx says, and actually all that could be said from the viewpoint of the systematic-dialectical exposition, concerning the quantitative determination of value, at least until chapter 3. In effect, we have already noted that the analysis can only uncover the ‘what’ of a determinate phenomenon. But only the synthetic development of the unity between the discovered content and its concrete forms of existence can account for the 'why' and the 'how'. Nevertheless, one could wonder whether the discovery of private labour which marks the specificity of the capitalist organisation of social labour could cast additional light on the ground of the magnitude of value. More concretely, the question is how can the social recognition of the quantity of necessary labour be established in a society with no direct collective power which could determine the productivity and intensity with which to exert the labour-power possessed by the different individuals? In these circumstances, the only way the normal conditions of production can assert themselves is through the constitution of an average out of the multiplicity of diverse independent singularities which tend to converge towards the said normality (Iñigo Carrera 2021, 49).

Two additional issues must be thrown into relief. First, no matter how concise Marx's discussion of the magnitude of value in chapter 1 of *Capital* is, the point remains that the *content* of the quantitative value-determination has been fully unearthed by that stage. In this sense, nothing in the subsequent systematic exposition can alter the initial potentiality of the commodity. The only thing that could change and be brought more fully into view, is its necessary *form of realisation*. Second, Marx's (1976a, 131) presentation in chapter 1 already shows that for the product of labour to be a bearer of value, it must be a *social use-value*, i.e. it must satisfy the need of a different individual from its producer. From the standpoint of *commodity-producing labour*, this means that it must be *useful for others*. That is why one could legitimately refer to a second sense in which commodity-producing labour must be 'socially necessary'. However, this has absolutely nothing to do with the determination of the magnitude of the commodity's value. Yet, circulationist readings conflate these two clearly different meanings to assign 'effective demand' a role in the quantitative determination of value. But the latter is a phenomenon of circulation, which we have already seen has no place in the constitution of value as a social form. In fact, at this initial 'level of abstraction' the dialectical presentation has not even led to face such thing as 'demand', so it could hardly enter as an element of the simplest content of value. At stake in chapter 1 is only the *expression* of value, and therefore the *constitution of the price-form as such*. 'Demand' has the latter as its systematic premise; it concerns the concrete form of realisation of the price-form in the effective practical movement of the circulation of commodities.

In this sense, it is crucial to distinguish among the different systematic steps in the constitution, ideal expression and effective realisation of the determinations of value. To do this, in the 1859 *Critique*, Marx differentiates between what he calls the 'theoretical phase of circulation of commodities' and the actual circulation process. The 'theoretical phase of circulation' of commodities is then deemed 'preparatory to real circulation' (Marx 1987, 303), since the latter can only take place once, 'as a result of the establishing of prices, commodities have acquired the form in which they are able to enter circulation' (323). Only then (section 2 of chapter 3 of *Capital*) is the actual movement of circulation of commodities reproduced in thought, revealing the subsequent functions of money not as its preconditions (presupposed more abstract forms) but as its results (its developed concrete forms). By that point, the question no longer resides in elucidating the 'what' of the quantitative norm that constitutes the magnitude of value, but rather in shedding further light, albeit preliminarily and incompletely, on the 'why' and, primordially, on the 'how'.

As Marx (1976a, 189–90) stresses on the section on the 'Measure of Value', although the 'price or money-form' of commodities is a 'purely ideal or notional form' in which value is *expressed*, the latter is nonetheless *determined* by the (socially necessary) 'quantity of human labour' *materially* contained in (socially-useful) products as they emerge from production. Thus, the *unity between the immanent qualitative and quantitative determinations of value*, which constitutes the *objective* inner content that is *outwardly* expressed in the monetary form of the 'normal price' of a commodity, must evidently be the *systematic premise* of the formal possibility of, and actual necessity for, a 'quantitative incongruity between price and the magnitude of value' (196) *in circulation*. In other words, from a systematic-dialectical perspective, already-determined normal prices (both qualitatively and quantitatively) must constitute the explanatory presupposition of market prices that deviate from them by virtue of a disequilibrium between 'supply and demand' manifested in circulation (cf. Marx 2015, 298).

As a matter of fact, this methodological angle underpins Marx's 'thought experiment' in chapter 3, through which he eventually follows the movement of the *effective* circulation of commodities. A certain number of pieces of linen arrive at the market *with their value already and solely determined* by the 'materialisation of the same socially determined quantity of homogeneous human labour' (Marx 1976a, 202) contained in each of them, which are in turn monetarily expressed in a 'normal price' of 2 shillings. On that basis, Marx *then* supposes that the 'market cannot stomach the whole quantity' of articles at that normal price, which *implicitly* leads, through the competition process among weavers, to a fall in the market price of the yard of linen below the magnitude of value.

Marx (1976a, 203) then closes his thought experiment with the observation that, from that moment on, he shall consider the phenomenon 'in its pure shape'. This involves abstracting from the 'abnormal loss or accretion of substance' of value which may result from the 'change of form' of the commodity, if the latter 'is not impossible to sell' (203).[12] Marx thus leaves the matter at that and proceeds with the further unfolding of the individual commodity's metamorphosis. However, there are a couple of additional points which could be made in this regard.

First, it must be stressed that it is not that the commodity 'loses/gains magnitude of value', but that its change of form *entails*, respectively, a 'loss or accretion of value' for the seller or buyer of that commodity. What one abnormally loses is what the other gains and vice versa. Second, and beyond Marx's (1989b, 132) explicit focus, when circulation is grasped from the standpoint of the overall unity of social production and consumption, an additional quantitative meaning of 'socially necessary labour' comes to the fore. Briefly stated, there emerges another 'quantitative norm' in the articulation of the general social division of labour, namely: the proportional allocation of the total social labour into the different branches of production. This reveals that the establishment of the unity between social production and consumption entails a definite magnitude of what becomes determined as the *normal social need* for each kind of use-value. At this level of abstraction, this corresponds to what is required for the reproduction of the productive attributes of commodity producers. Furthermore, this brings to view the organic character of each individual commodity as an aliquot part of the quantitatively-determined normal mass of commodities of a qualitatively certain type. From the standpoint of commodity-producing labour, this shows that the quantitative determination of value-production is not a process which simply concerns each 'isolated' commodity but pertains to the organic (sub)unity of each branch of social labour (Marx 1976a, 202; 2015, 302). Still, although this quantitative determination of the normal social need is *discovered* through the examination of circulation, it is an *immanent material determination of the organisation and execution of direct production*. As already argued, production is the point of the departure and ground of the unity of the process of metabolism and, therefore, also of social consumption.

Now, a partial overproduction of a certain kind of use-value *vis-à-vis* the normal social need does not imply that there has been no value-production corresponding to that excess 'supply'. Instead, it means that too much value has been produced compared to the normal scale in that sphere; or, as Marx (1976a, 202) puts it, that 'all these pieces taken as a whole […] contain superfluously expended labour-time'. Thus, this value does not just simply vanish into thin air but is appropriated in another node of the social division of labour. In effect, the very existence of a normal inter-branch proportional distribution of social labour implies that the excess in value-production in one node must involve a correspondingly insufficient scale of value-production in another. The competition-driven divergence of market prices from normal prices that directly express the immanent magnitude of value 'constantly regulates this distribution' of 'necessary labour time […] among the various spheres of production' (Marx 1989b, 132). Under these circumstances, and from the viewpoint of the unity of social production and consumption, *all privately-undertaken material expenditure of SNALT proves to have been socially-useful in a qualitative sense*. In terms of its 'purely social' representation as the 'exchangeability' of its product, the total mass of value materially borne by all *socially-useful* products of private labour is realised in circulation, although it is (partly) appropriated in different spheres from those in which it had been produced. In sum, the imbalance between 'supply and demand' is but the self-negating form in which the proportional distribution of social labour-time is established when mediated by generalised commodity production.

At this juncture, a final methodological observation is in order. Note that Marx's analysis in chapter 3 stops short at the indication of a necessity for a quantitative divergence between market prices and normal prices and does not unfold the adjustment mechanism which tends to eliminate the underlying imbalance between production and social need for the respective use-value. Presumably following his own methodological remark in the 1859 *Contribution* that the 'coming into being' of a 'market price differing from exchange value' must be 'solved in the theory of competition' (Marx 1987, 302), that mediating process is not fleshed out until Volume III, once Marx has already developed the exchange of commodities as the product of individual capitals determined as formally undifferentiated aliquot parts of the total social capital, i.e. through the formation of the general rate of profit. In effect, the competition over the appropriation of the general rate of profit is the concrete form in which the requirements for the normal material reproduction of society are imposed upon capitalistic private producers (i.e. individual capitals). This applies both to the SNALT required to produce each commodity and to that which is needed for the total mass of commodities in the respective sphere of production.

As is widely acknowledged, the comprehension of this text is far from straightforward. From very early on, commentators have indicated that there are certain parts where Marx seemingly sees the movements of supply and demand as somehow determining the magnitude of value (cf. Rubin 1972; Rosdolsky 1977). This is why these passages are sometimes offered as textual evidence by contemporary circulationist readings or, alternatively, by 'intermediate' positions which claim that the market conjuncture defines which condition of production determines SNALT. We cannot examine this exegetical issue here in any depth. However, by situating in context those controversial passages, we would like to offer a reading which is consistent with the broader perspective spelt out in the previous two chapters.

First and foremost, it is to be noted that in those passages which are usually read as pointing to the determination of value by supply and demand, Marx (2015, 289; 295–96; 301) always refers to *extremely exceptional circumstances*. By contrast, in normal circumstances, which include conjunctural imbalances between supply and demand, Marx is unequivocal that value is entirely independent of market conditions (291; 297–304). Moreover, concerning those extreme circumstances, Marx never speaks of 'value' but of 'market value'. The latter does not seem to imply an immediate quantitative identity with so-called 'social value', as evidenced by Marx's subsequent discussion of agrarian production, where he states that the 'law of market value' implies the existence of a 'false social value' (817). For these reasons, we do not find his rather ambivalent recourse to the category of 'market value' persuasive (or necessary for that matter). In this sense, in our reconstruction of Marx's manuscripts, we shall treat so-called 'market value' as synonymous with the 'normal direct price' of commodities, i.e. as the simplest monetary expression of their social value, which is what Marx does when considering the normal conditions of commodity exchange (291–93).

Marx analytically distinguishes between intra-branch competition, which mediates the realisation of the social value of commodities, and inter-branch competition, through which prices of production come about. That latter presupposes the distinction between such social values and market prices (Marx 2015, 304). Regarding intra-branch competition, Marx distinguishes between an individual value, which expresses the privately-undertaken individual labour-time embodied in a commodity, and a social value, as the social representation of the latter which is determined as socially necessary. In turn, insofar as the point is to mediate the actualisation of the social value through competition, it is necessary to distinguish between a market price, which is the immediately visible mode of existence of value, and a *normal direct price* (i.e. Marx's 'market value'), as the simplest monetary expression of social value in circulation, which is the gravitational centre around which the former fluctuates.

Now, commodities reach the market as the result of diverse conditions of production. Consequently, their normal price or market value will reflect the average of their respective individual values. Hence, if commodities produced under mean conditions have the greater weight, whilst those in the respective ends of the spectrum cancel each other out, the market value will be 'regulated' (in the simple *arithmetic* sense) by the former. By contrast, if any of the extreme conditions is predominant, they will have the 'upper hand' in the constitution of the market value. As Marx (2015, 289) observes, individual capitals will consequently gain/lose value to the extent that the individual value of their commodities stands below/above the resulting market value.[13] Through these divergences, the norm that constitutes SNALT is imposed upon individual capitals.

Once the formation of the market value has been elucidated, it remains to be considered the mode in which the former takes concrete shape through market prices. Another quantitative difference emerges, but now concerning the normal conditions for the unity between social production and consumption. In other words, at stake here is the relation between the total social labour that has been privately expended in the production of a certain kind of use-value, and the normal magnitude of the (solvent) social need which is meant to satisfy. An imbalance will be expressed through a divergence between the respective market price and the normal price or market value which constitutes the simplest monetary expression of the social value (Marx 2015, 291; 297–304). Thus, this divergence between an already-constituted market value and market prices, which will also be expressed in the individual capital's capacity to obtain the average rate of profit, will be the mode in which the *normal* magnitude of social labour which must be allocated to a certain branch of production, will be imposed upon individual capitals.

Notes

1 For an in-depth assessment of Rubin's work, see Kicillof and Starosta (2007) and Starosta (Forthcoming). As argued in those articles, Rubin cannot be simply read as a precursor of the circulationist perspective on the value-form; as a matter of fact, it is possible to find in his work a more production-centred approach. However, the seeds of the former perspective are certainly there, so that there is a tension running through Rubin's work. Thus, circulationist formulations (fundamentally, when discussing the *qualitative* determination of value, i.e. the problem of its *constitution* or *genesis* as a historically-specific, reified form of social mediation) uneasily *co-exist* with other places where the opposite perspective seems to prevail (primordially with reference to the *quantitative* determination of the *magnitude* of value).

2 Here we shall focus solely on the general thrust of Heinrich's approach which shares in the most common substantive arguments of the broader circulationist strand of thought. In other words, we shall not engage with the excessively idiosyncratic and overly polemic aspects of his textual exegesis of Marx's *Capital*. For a detailed critical examination of the philological and exegetical weaknesses of Heinrich´s reading, along similar substantive lines as the ones adopted in this chapter, see Moseley (Forthcoming).

3 In a similar vein, a person can engage in a conversation in English (i.e. establish a 'communicative relation' with another English speaker) by virtue of being already 'immanently' determined as an Anglophone prior to and outside the conversation itself. The constitution or positing of the general aptitude or potentiality to speak English

must thereby be a presupposition of the actualisation or activation of that ability in a particular conversation with another Anglophone. Surely this must be the implication of Marx's (1976a, 149) dictum that 'the properties of a thing do not arise from its relations to other things, they are on the contrary, merely activated by such relations'. In other words, relations merely activate and express potentialities or capacities intrinsic to 'individual entities', they do not engender them. That at stake here is a social rather than a natural property is immaterial in this regard. In this sense, a commodity can take on the 'non-natural' role of the direct material incarnation of abstract socially necessary private labour in opposition to the commodity in the relative form, for being such bearer of value itself *prior to* entering a value-*relation* and 'subsequently' playing the social role of equivalent in the value-*expression* of the other commodity. The different 'moments' of these determinations in their unity are nicely and concisely captured in the following passage by Marx from the *Theories of Surplus Value*:

> But for commodities to express their exchange value independently in money, in a third commodity, the exclusive commodity, the *values of commodities* must already be presupposed. Now the point is merely to compare them quantitatively. A *homogeneity* which makes them the same – makes them values– which as values makes them qualitatively equal, is already presupposed in order that their value and their differences in value can be represented in this way […]. Otherwise it would be impossible to solve the problem of expressing the value of each commodity in gold, if commodity and gold or any two commodities as values were not representations of the same substance, capable of being expressed in one another. In other words, this presupposition is already implicit in the problem itself. Commodities are already presumed as values, as *values* distinct from their use values, before the question of representing this value in a special commodity can arise.
>
> (Marx 1989a, 321)

4 As we have seen in the previous chapter, the 'expression of equivalence between two different sorts of commodities […] *brings to view* the specific character of value-creating labour' by reducing 'in fact' the different concrete labours embodied in two heterogenous commodities to '*what is really equal in the two kinds of labour*' (Marx 1976a, 142, emphasis added). Heinrich circulationist understanding of this sort of recurring formulation in Marx's *Capital* is flawed in at least two main respects. First, he replaces the idea that the exchange relation brings to *view* (i.e. outwardly expresses in a socially-recognisable manner) the specific character of value-creating labour, with that which considers that it brings the latter into *existence*. Second, and concomitantly, that 'common quality of being human labour in general' is not seen as a characteristic that the different kinds of useful labour *have* in and of themselves, and which thereby constitutes what *is* really equal in them at the only moment in which they objectively and materially exist *as labour*, i.e. in the sphere of production. Note, moreover, that this is also true of the historically-specific significance of the abstract character of labour in the organisation of the unity of social production and consumption: individual private labours relate as organic elements of the total labour of society on the basis of their common physiological quality as human labour in general already at the point of production. Instead, his argument implies that 'this equal counting of the various types of labor is not something preexisting […] it is *only through exchange* that the abstracting from real inequality takes place, creating the equality of labor activities' (Heinrich 2021, 156–57). In brief, he is led to conclude that an aspect of labour *comes into existence* when labour as such *no longer exists*.

5 The following section draws on Starosta (Forthcoming).

6 For instance, an exam validates whether a student already had knowledge of the respective subject as an 'immanent' quality of their subjectivity before submitting their paper. Considered the matter in its 'purity' (i.e. abstracting from nervousness during the

exam, cheating, unfairness in marking, etc.), if they did have that knowledge, they would pass; if they did not, they would fail. The exam is undoubtedly necessary to mediate the outer expression of that 'inner' personal attribute in a socially-recognisable form, but does not engender that knowledge-content, which can only be posited by an action (i.e. studying) that precedes that of taking the exam. On the other hand, when the matter is not analysed 'in its purity' (i.e. under the assumption of an immediate identity between content and form of the determination at stake), but with all the mediating circumstances entailed by the *concrete form* in which knowledge is manifested in the alienated (hence inevitably antagonistic) institutional practice of 'the formal act of assessment', the possibility arises for a 'quantitative or qualitative incongruity' between intrinsic knowledge-content and its necessary outer form of expression (compare Marx 1976a, 196–97, concerning the analogous relationship between value and price). Thus, the external measurement of the quantity of knowledge-content in a socially-recognisable form, i.e. the 'realised grade' obtained, might deviate from its immanent magnitude (determined, let us say, by the 'socially necessary exam preparation time'). Or, in the case of uncaught cheating or plagiarism, there could be a sheer qualitative contradiction between content and form.

7 We critically examine Kliman's perspective below.

8 Space restrictions do not allow us to make a comprehensive assessment of all existing contributions which deliberately seek to offer both a non-Ricardian and non-circulationist approach to the determination of value as a social form. We shall thus focus on the two which, we think, have provided the most sophisticated interventions and which, furthermore, have engaged in an explicit debate with each other.

9 As a matter of fact, it is unclear to us whether Murray himself would see his own stance as differing from Heinrich's which, for reasons fleshed out earlier in great depth, is unequivocally circulationist. Apart from Sohn-Rethel (1978), his explicit (yet still unsure) references to what he might see as more recent 'extreme circulationist' contributions come down to Eldred and Hanlon (1981), and Kay and Mott (2004). Moreover, he mentions that all other authors with whom Kliman, Posner and Gonzalez critically engage with (for instance, Geert Reuten and Chris Arthur), also hold a co-constitutive view.

10 We must admit that we find Murray's analogy between Hume's 'distinctions of reason' and Hegel's 'moments' rather odd. For whilst Hume explicitly conceives of the former as the products of subjective reflection, Hegel sees the latter as constitutive of the actual form-determinations of the object of cognition (Westphal 2005). Thus, right at the outset of his *Science of Logic* he already chastises the '*reflective* understanding' which 'behaves as ordinary common sense and imposes its view that truth rests on sensuous reality, that thoughts are only thoughts' (Hegel 1999, 45).

11 The explicit conceptualisation of value-positing in production as '*real or concrete possibility*', whose realisation would be still pending until exchange, can be found in the work of Bellofiore (2018, 535).

12 Were the product of private labour quite simply 'impossible to sell', it would mean that it was not a social use-value nor, therefore, bearer of value, from the very outset in production.

13 As we shall see in Chapter 8, this process only involves normal capitals, i.e. those which partake in the active development of the productive forces by virtue of their scale, in contrast to what we shall term 'small capitals'.

3 Systematic and historical modes of explanation in the critique of political economy

A methodological contribution to the controversy over the commodity nature of money

Introduction

This chapter discusses Marx's account of the genesis of money in the first two chapters of *Capital* from a methodological perspective. In particular, it focuses on the connection between systematic development and historical explanation in the dialectical exposition. To do so, we set our discussion within the frame of an interesting and extended academic debate on the essential nature and historical origins of money which took place a couple of decades ago among Marxist political economists and economic sociologists (Dodd 2005; Fine and Lapavitsas 2000; Ingham 2001; 2006; Lapavitsas 2005; Zelizer 2000). Among the various controversial issues that emerged in the debate, we would like to centre on the exchange between Costas Lapavitsas and Geoffrey Ingham on the essential nature of money. These two authors represented, respectively, the view according to which money fundamentally is a commodity and originates in commodity exchange, and that which claims that it primordially is a token claim on goods founded on public authority. Of course, these opposing perspectives on money have a longstanding lineage in the history of monetary thought. As Schumpeter (1918, 649) eloquently puts it, these are the 'only two theories of money which deserve the name'.

The controversy between Lapavitsas and Ingham constitutes a helpful and relevant scholarly frame for discussing the nature of money not only for incorporating relatively recent research and arguments in support of, and against, each of the two contrasting perspectives in this longstanding debate. It also stands out for bringing to the fore and calling into question Marx's original account of the genesis of money. More importantly for the theme of this chapter, these authors sought to ground their own approach to money in both theoretical and historical arguments, which ended up giving the discussion a strong *methodological* edge. As Ingham (2001, 306) himself acknowledges with reference to the prior 'incarnation' of this debate in the so-called German *Methodenstreit* between the late 19th century and the early 20th century, at the heart of the polemic lies 'the dispute over the "logical" and "historical" origins of money'.

To structure our own argument, this chapter is organised in the following manner. After revisiting the main theoretical and empirical arguments put forward by the main participants in this controversy, we conclude, in agreement with Lapavitsas,

DOI: 10.4324/9781003201939-4

that money must be effectively considered a commodity and, furthermore, that as argued in Marx's *Capital*, its genesis must be searched in the immanent contradictions of commodity production. However, based on a critical examination of Lapavitsas's perspective, we show that his defence of the Marxian approach leaves many weak flanks and does not stand on firm ground. Crucially, we trace the source of those weaknesses in the 'logical-historical' method that (implicitly) informs his reading of Marx's *Capital*.

Against the backdrop of these limitations in Lapavitsas's approach, we suggest that their overcoming involves a clear and rigorous distinction between 'systematic development' and 'historical explanation' of 'economic categories' in the critique of political economy. Moreover, and here in agreement with the so-called 'New Dialectics' literature (Arthur 2002; 2022; Moseley 1993; Moseley and Campbell 1997; Reuten 2019; Smith 1990),[1] we argue that the explanation of the genesis of money in the exchange of commodities must be provided in fundamentally *systematic* terms. However, we part company with this recent methodological literature in that we think that it fails to offer a convincing account of the actual part played by the historical strand of explanation that Marx included in *Capital*. In other words, this literature does not offer solid arguments to make sense of Marx's (1973, 460) well-known methodological remark from the *Grundrisse* according to which 'our method indicates the points where historical investigation must enter in'. In contradistinction to 'New Dialecticians', we submit in this chapter that, in effect, historical explanation plays a necessary role in Marx's dialectical exposition in *Capital*. More specifically, we argue that the explanation of the genesis of money precisely is one of those points 'where historical investigation must enter in'. The key issue, which is where we feel Lapavitsas misses the mark, is *why* and *how* historical explanation must enter the stage. This alternative argument is fleshed out through a methodologically-minded reconstruction of the Marxian account of money in the first section of *Capital*.

Lapavitsas and Ingham on the nature of money

The article that inaugurated the polemic was already quite expressive of the methodological angle that the subsequent discussion would later adopt. Thus, Fine and Lapavitsas (2000) postulate in their original contribution that a general theory of money must be based on the 'logical derivation' of its origin'. More specifically, it needs to 'logically demonstrate how and why exchangeability becomes monopolized by the money commodity' (365). According to Fine and Lapavitsas, this explanation can be found in Marx's development of the form of value in section 3 of chapter 1 of *Capital*. However, to the extent that these authors see Marx's exposition as involving the *historical* genesis of money and not just its actuality in capitalism, they further maintain that such unfolding of the form of value must be reconsidered in abstraction from the substance of value (367). Thus, they put forward an explanation of the origin of money which starts with the simple exchange of products, whereby the necessity fully to express the value of a commodity leads to its expanded manifestation in multiple commodities. Subsequently, to the extent that one particular commodity increasingly becomes designated by the rest as the expression of their value as the exchange process develops further, it ends up acting as the general equivalent or money (366). In sum, it is the intrinsic dynamics of commodity exchange which lead to the emergence and consolidation of a particular commodity as the general expression of the value of the rest of commodities.

Ingham's (2001) initial intervention aims his critique at this conception of the nature of money as a commodity which, moreover, would have originated in the exchange process. According to his alternative sociological approach, the nature of money lies in its quality as a 'pure token *claim* against goods', whose main function is to act as 'the means for the final – that is, unilateral – payment or settlement of debts, the most important of which are tax debts to the state' (306). In other words, regardless of its 'phenomenal form' money is seen essentially as *credit*. In turn, this essential nature of money as a promise to pay is incarnated in the particular 'item' that the public authority directly establishes as '*the means of accounting for value (money of account)* and the *various means or forms of the representation of abstract value* (abstract purchasing power that is accepted as means of payment/settlement of debt)' (307). Moreover, this conventional, state-sanctioned origin of money also lies at the basis of its *historical emergence*. Thus conceived, i.e. as the product of direct social relations between individuals, 'money of account is logically anterior and historically prior to the market' (309).

On these grounds, Ingham launches a critique of what he labels 'commodity-exchange theories' of money, epitomised in mainstream neoclassical economics. The main problem with that orthodox account, Ingham argues, is that it purports to explain an irreducibly *social* phenomenon on the basis of *individual instrumental rationality*:

> However, it is not so much a question of whether it is advantageous to use money if others do, but rather that agents cannot use money unless others do likewise. To state the sociologically obvious: the advantage of money presupposes monetary institutions.
>
> (Ingham 2001, 308)

On the other hand, to reject the idea of the historical origin of money in commodity exchange, Ingham refers to certain studies which attempted to demonstrate that money had functioned as a pure 'money of account' in non-mercantile contexts. Among them, Ingham focuses on Grierson's (1977) analysis of the institution of *wergeld* in Germanic tribal societies. This institutional arrangement involved the establishment of a system of 'tariffs for the precise measurement of debts to be paid in compensation for injuries and damages' (Ingham 2001, 310), which took place in public assemblies. Regardless of the actual 'stuff' which functioned to settle those 'debts', which could comprise diverse articles, all compensations for injuries were measured on a scale of tariffs denominated in the same 'unit of account'. Hence, in these non-mercantile historical contexts, money seemed to have functioned as *means of account* without (and before) serving as 'means of circulation' (310–11). Indeed, according to Grierson's account, 'the conditions under which these laws were put together would appear to satisfy much better than the market mechanism, the prerequisites for the establishment of a monetary system' (Grierson 1977, 20–21, cited in Ingham, 2001, 311).

In response to Ingham's criticisms, Lapavitsas (2005, 392) insists that his own explanation of the nature of money 'is both materialist and Marxist because it shows money to be the outcome of social relations among commodity owners'. The latter are now specified 'as "foreign" individuals', i.e. who mutually relate in the exchange process based on 'the absence of pre-existing ties of kinship, hierarchy, tradition and morality' (392). However, in his response, Lapavitsas clarifies that the explanation of the nature of money cannot be exclusively developed in *logical* terms. In effect, according to this author, the transition from the 'expanded' to the 'general' form of expression of value, i.e. the genesis of money, entails an insurmountable contradiction from the point of view of the pure commodity exchange between 'foreign individuals'. Money, Lapavitsas continues, 'represents asymmetry among commodities [...]. But commodities are intrinsically symmetric as objects of trade' (393). Consequently, this view leads him to conclude that the transition (alongside de ensuing asymmetry between money and 'ordinary' commodities that it involves) must incorporate 'extra-economic factors'. In other words, the emergence of money must be accounted for 'partly from economic processes and partly from non-economic relations, including social custom' (394).

Lapavitsas then turns to the critique of Ingham's views, which can be summarised in the following three points. First, he points to the 'extremely tenuous', 'arbitrary' and 'misleading' link between money's postulated function as 'abstract unit of account' and 'credit relations' (Lapavitsas 2005, 396). Second, he notes that the historical evidence presented by Ingham is beset with ambiguities and points out that 'merely showing that the unit of account happens to be differently denominated from the means of exchange is no such evidence' (396). At any rate, what Ingham should have demonstrated is 'the existence of money of account that did not originally function as means of exchange, i.e. money of account with purely ideal units, products of human consciousness alone' (396). Finally, and third, Lapavitsas criticises Ingham for conflating the functions of 'measure of value' and 'standard of prices'. Money, he clarifies, 'acts initially as ideal measure of value, but if exchange is to have economic content, money must also act as standard of price in practice, thereby rendering prices real' (397). In this sense, it is no wonder, Lapavitsas adds, that when we examine the real course of monetary phenomena throughout history, it transpires that 'the conventional aspect of the standard of price is associated with the physical aspect of the money stuff as well as the social customs that surround its use as plain commodity' (398). For all these reasons, he concludes, 'Ingham's favoured approach faces insuperable difficulties in developing a logical account of how such an ideal unit could have been devised in practice' (399).

In his rejoinder article which formally draws the debate to a close, Ingham (2006, 262) persists in his argument that simple commodity exchange cannot generate a money-commodity and reiterates that Lapavitsas's stance on the matter is 'indistinguishable in its analytical structure from the orthodox neoclassical economic creation myth of money's origins in barter exchange'. However, he now acknowledges the limitations of an argument that relies on historical evidence to settle the question since, by virtue of the inherent limits to this kind of evidence, 'the precise historical origins of money will never be known' (262). Still, he maintains that 'any analytical construction of money's logical conditions of existence must be consistent with historical knowledge – however inadequate this may be'. In this sense, although Lapavitsas accepts the need to have recourse to history to produce a general theory of money, the evidence he provides barely goes 'beyond references to "social custom" and the reiteration of the commonplace assertion that commodity exchange arose when communities came into contact' (265).

The methodological limits of the explanations put forward in the debate

At this juncture, the debate seems to have reached a dead end. Both authors seem to concede that the initial arguments offered to make their respective cases about the nature of money fall down. In effect, Lapavitsas ended up admitting that his explanation of money cannot be, as demanded at the beginning of the polemic, of a purely 'logical' character. For his part, Ingham concluded that his own account cannot actually be confirmed by available historical evidence, which was the main thrust of his initial intervention.

More specifically in the case of Lapavitsas, the shortcomings of his initial stance are blatantly patent in his eventual recognition that, in order to explain the origin of money, the argument inevitably needs to bring in *relations of personal dependence*. Yet, this kind of social relations stand absolutely opposed to the essential character of pure commodity relations, which should be the only kind entailed by the 'logical derivation' of the expression of value in the form of exchange-value, i.e. in and through the exchange relation between different commodities. In this sense, one could argue that in his response to Ingham, Lapavitsas confronts an insurmountable tension: either he sticks to the idea that money springs solely from exchange relations between simple commodity owners, but fails to dodge Ingham's accusation that this kind of explanation hardly differs from neoclassical economics; or, as he ends up doing, he grants that in order fully to account for the genesis of money the recourse to 'extra-economic' relations cannot be avoided. But the latter amounts to validating Ingham's point that money cannot be logically derived from commodity exchange and, furthermore, that indirect relations through the commodity-form are ultimately grounded in *direct* social relations.

However, Ingham's own perspective is not free from difficulties either. At first, his argument mostly rested on empirical claims about socio-historical experiences unrelated to commodity exchange, which appear to accommodate the requirements of a sound explanation of the genesis of money better than the respective accounts of neoclassical economics or Lapavitsas. However, when scrutinised more closely, those pieces of empirical evidence proved not to be as conclusive as initially intended. Above all, the money of account used in those non-mercantile societies indicated by Ingham did not necessarily become money which functioned as a pure promise to pay; or rather, that transition is precisely what needs to be explained. More importantly, in all the historical examples that Ingham brings up, such money of account always refers to a product of labour; quite remarkably, to the kind of product which accounts such as Lapavitsas's identify as the kind which emerges as money out of the exchange process (for instance, silver –by virtue of its physical features–, or wheat –due to its condition as the most widely exchanged commodity). At this juncture, it is striking that Ingham fails to mention the existence of what Grierson (1978, 10) himself calls 'money substitutes', i.e. commodities that replace money of account in the exchange process. As a matter of fact, this alone indicates the extent to which commodity exchange had developed in historical conjunctures in which 'pure' money of account had allegedly emerged. In turn, it calls into question the supposed impossibility for money to develop out of the process of exchange. In this sense, it seems that for Ingham one can only speak of money proper when a legal standard of prices comes into being, which leads to an utterly tautological explanation: money emerges as a legal standard of prices because money is, *ex definitione*, a legally-established money of account. Still, if as he ends up declaring, the historical origin of money will never become known with any certainty, all empirically-grounded discussion over its emergence turns out to be rather otiose.

In sum, in light of this controversy between Ingham and Lapavitsas, the task of providing a sound explanation of the nature and genesis of money, be it 'logical' or 'historical', appears to be, quite simply, beyond reach. Yet, we think that this *substantive* impasse in the search for a valid explanation of money as a social form is not an insurmountable barrier to rational knowledge but expresses the flaws in the *form* in which *both* authors approach the subject matter in question. For regardless of all discrepancies in their stances and conclusions on the nature of money, they share a similar view of what a proper explanation should be, namely: one in which the logical and the historical approaches to the emergence and constitution of a certain social phenomenon go hand in hand to form a single, undifferentiated account. In other words, implicit in both authors is the view that the sequence of systematic 'moments' or determinations whose unity constitutes the present-day reality of social phenomena matches the series of stages undergone in their historical development. However, as we shall argue in what follows, this perspective is *methodologically* flawed from the standpoint of the critique of political economy.

Indeed, in the past decades, this issue has been at the centre of methodological discussions within Marxist theory, especially among scholars coming from the so-called 'New Dialectics' approach. Despite the diversity of views within this current of thought, all these scholars share a critical view of the kind of methodological conception that is implicit in both Lapavitsas and Ingham. As 'New Dialecticians' have pointed out, a similar conception had been part and parcel of the Marxist common sense prevailing in debates over the dialectical method throughout most of the 20th century. As they have also noted, the origin of this methodological perspective can be traced back to some remarks in the work of Engels. More specifically, in one of his renowned reviews of the 1859 *Contribution to the Critique of Political Economy*, Engels (1980, 475) observed: 'Even after the determination of the method, the critique of political economy could still be arranged in two ways – historically or logically.'

'New Dialectics' scholars' critique of this Engelsian methodological conception has focused on its implications for the understanding of the architecture of *Capital*. In particular, they have called into question the notion that the first section of Volume I corresponds to the analysis of a historically-existing pre-capitalist society of simple commodity producers, an interpretation that Engels (1991a, 103; 1991b, 1037) himself suggested in some of his writings. This misguided conception involved not only an empirically inaccurate characterisation of capitalism's prehistory but also led to an impoverished understanding of Marx's value theory for capitalist society. Whilst several highly-influential authors like Kautsky (1903, 5), Lenin (1977, 27), Hilferding (1949, 195), Luxemburg (2013, 249ff.), Meek (1967, 96) and Mandel (1971, 63) shared this view, 'New Dialecticians' have emphatically rejected it (Arthur 1996, 191). As Smith (1990, 94) puts it, 'the simple commodity form does not model the development of some precapitalist stage of simple commodity production. Nor can the logical development of the money-form be justified in terms of a logic of historical stages'. More importantly, all these authors take issue with the methodological orthodoxy inspired by Engels for standing in blatant opposition to 'one of Marx's main methodological tenets', which is 'that the sequence of economic categories is determined by their inner connection within capitalist society and not by whatever sequence occurred in historical development' (Robles Báez 1999, 101). Indeed, this line of argument was explicitly fleshed out by Marx in one of his better-known and more relevant methodological remarks:

> It would therefore be unfeasible and wrong to let the economic categories follow one another in the same sequence as that in which they were historically decisive. Their sequence is determined, rather, by their relation to one another in modem bourgeois society, which is precisely the opposite of that which seems to be their natural order or which corresponds to historical development. The point is not the historic position of the economic relations in the succession of different forms of society. Even les is it their sequence 'in the idea' (Proudhon) (a muddy notion of historic movement). Rather, their order within modern bourgeois society.
>
> (Marx 1973, 107–8)

On these grounds, this literature broke further with the canonical interpretation of the dialectical method by distinguishing between a 'systematic dialectic' and a 'historical dialectic' (Arthur 1996; 1997; Reuten 2000; 2014; Robles Báez 1999). In other words, they suggested that Engels's 'logical-historical method' should be doubled into two different methods. Whilst the systematic dialectic is 'a method of exhibiting the inner articulation of a given whole', the historical dialectic is 'a method of exhibiting the inner connection between stages of development of a temporal process' (Arthur 1996, 182–83). Seen in this light, 'New Dialecticians' conclude that in *Capital* Marx only used the 'systematic-dialectical method', whereas the 'historical dialectic' would have been used only partially in other writings. In this sense, this approach suggests that 'in a systematic theory historical considerations can have only an illustrative function' (Smith 1990, 194). Consequently, the 'historical material' in *Capital* has no other role than 'indicating how certain tendencies inherent to the concept were played out in reality' (Arthur 2002, 76).

If we set aside the idealist veneer involved in the characterisation of materialist dialectics as a type of 'logic', the main problem with this approach is that it splits the dialectical method into two opposing and unconnected methods. In other words, instead of showing which concrete role historical analysis plays in the dialectical unfolding of present-day form-determinations, it 'settles' the question by simply excising the former from the latter. At most, it boils historical analysis down to the role of 'illustrating' that which had already been systematically discovered and demonstrated. From the point of view of the methodological legacy left by Marx, this has at least two fundamental weaknesses. In the first place, there is no textual evidence which could suggest that Marx considered that there were two different methods of investigation, whatever their nature. Rather, he tended to refer to one and only materialist, hence scientific, method (Marx 1976, 494n). In the second place, it fails to offer a convincing explanation of the *necessary* role played by Marx's interjection of historical lines of development of *pre-capitalist* phenomena in the *systematic* exposition in *Capital*. By definition, those historical accounts of past modes of production cannot constitute 'illustrations' of the form-determinations of the *capitalist system*.

In this sense, Reuten's contribution stands out for seemingly acknowledging, although rather casually and in-passing, that those historical analyses that appear in *Capital* have more to offer than merely illustrating the systematic 'categorial' development. 'Historical materialism', Reuten argues, overarches 'systematic dialectics with regard to transitions between modes of production'. The latter method can 'present *extant* contradictions and conflict and the way they are settled within the system, but it is unable to present transitions from one system to another' (Reuten 2000, 151). Thus, Marx's exposition of the so-called 'primitive accumulation' can be read as an explanation that is informed by the method of 'historical dialectics' and which accounts for the transition from a pre-capitalist mode of production to capitalism. In this light, it could be regarded as an explanation which is 'complementary' to the pure systematic exposition, although Reuten tends to see this as symptomatic of the *limits* of the systematic-dialectical method. In effect, as this author himself recognises, that reading resonates with the following Marxian methodological remark from the *Grundrisse*: 'On the other side, much more important for us is that *our method indicates the points where historical investigation must enter in*' (Marx 1973, 460–61, emphasis added).

However, we think that Reuten's reading of that passage fails to bring clearly to light some crucial aspects of what Marx is trying to convey. In the first place, as mentioned earlier on but which is now confirmed by textual evidence, Marx does not refer to two different *methods* but to what we could term ‘moments’ within a single process of the dialectical investigation and its exposition. Furthermore, the so-called ‘primitive accumulation’ is not the only stage in the dialectical presentation in *Capital* at which ‘historical investigation must enter in’. Consequently, it is not entirely correct to state, as Reuten does, that the exclusive role of the latter kind of investigation is to explain transitions between modes of production. As we shall see, the other point in Volume I at which ‘historical analysis’ must come into play precisely is the explanation of the *contemporary reality of money*. This means that the relationship between systematic and historical explanation suggested by ‘New Dialecticians’ fails both as a reading of Marx’s method in *Capital* and, above all, as a way of apprehending the present-day constitution of money as a social form.

The contemporary reality of money

Money is the general form of expression of value common to all commodities. Fine and Lapavitsas are therefore right when they claim that the explanation of money must be searched in Marx’s examination of the ‘value-form, or exchange-value’ of the commodity, i.e. in section 3 of the opening chapter of the first volume of *Capital*. Indeed, right at the outset, Marx (1976, 139) stresses that through this exposition ‘the mystery of money will immediately disappear’. Moreover, he notes that this development constituted his own original contribution, inasmuch as it was ‘a task never even attempted by bourgeois economics’ (139). However, we think that the reading of those pages of *Capital* that Fine and Lapavitsas offer suffers from significant shortcomings.

First and foremost, when these authors state that in those pages Marx is attempting to ‘logically demonstrate how and why exchangeability becomes monopolized by the money commodity’ (Fine and Lapavitsas 2000, 365), they fall back into a reading which, similarly to Engels’s, conflates the unfolding of the present determinations of money with their historical development. As we have seen, several scholars have forcefully taken issue with this logical-historical reading of those pages of *Capital*, especially those writing from the ‘New Dialectics’ current discussed earlier on (see Robles Báez 1997; Smith 1990, 94). More recently, Heinrich (2021) has emphatically put forward a similar critical argument through a detailed exegetical commentary on Marx’s text. First and foremost, Heinrich notes, Marx ‘never says anywhere that he aims to provide a *historical* narrative recounting money’s emergence’ (97). Additionally, this scholar perceptively comments that ‘the history of money begins in pre-capitalist times, but Marx has said many times that his object of investigation is the commodity *in capitalism*’ (97). Finally, he rather bluntly points out that if the ‘genesis of money’ contained in section 3 of chapter 1 ‘were a brief history of money’, then Marx’s statement about bourgeois economics not having attempted such a task would be simply wrong, since ‘histories of money had existed for a long time, and Marx knew the literature very well’ (97).[2]

This first weakness of Fine and Lapavitsas leads us, in turn, to an additional highly problematic aspect of their approach. Once we rule out the idea that the unfolding of the necessity of the monetary expression of value runs parallel and/or is grounded in the historical development of money, the suggestion that it is preferable to reconstruct Marx's exposition in abstraction from labour as the substance of value loses whatever sense it could have made. Indeed, we shall see that this methodological procedure turns the examination of the form of value into a sheer formality which, moreover, ends up obliterating key elements of the argument that Marx is spelling out in those pages.[3] This is hinted at by Ingham, although this insight is somehow overshadowed by his otherwise traditional or 'Ricardian' reading of *Capital*. Most important of all for the theme of this chapter, we shall show that the consideration at this initial stage or 'level of abstraction' of labour as the substance of value is not only relevant for the comprehension of the form of value but also, crucially, for grasping the commodity nature of money. Let us, therefore, turn to this fundamental point through a closer scrutiny of Marx's dialectical investigation of the determinations of the commodity in the first chapter of *Capital*.

As noted in Chapter 1 of this book, Marx (1975, 198) begins his exposition with the immediate observation of 'the simplest social form in which the labour-product is presented in contemporary society', i.e. with the individual commodity as it appears 'at first sight'. From that starting point, Marx then proceeds to the *analysis* of the commodity. In its characteristic *dialectical form*, this analytical movement consists in the discovery and separation of the determinate content which is expressed – hence exists– in the mode of the concrete social form under scrutiny.

In this manner, Marx thus lays bare that behind the immediate manifestation of its social attribute as exchange-value lies its historically-specific property of general exchangeability, which he calls *value*. In turn, further analysis of value reveals that its substance or content resides in the privately-undertaken socially necessary abstract labour congealed or materialised in the commodity. However, as Iñigo Carrera (2021, 87–88) points out, this analytical phase is unable to answer the question which subsequently arises and which political economy 'has never once asked', namely: 'why this content has assumed that particular form, that is to say, why labour is expressed in value' (Marx 1976, 174). The course of the dialectical exposition thereby leaves the analytical stage behind and undertakes the 'return journey' through the *synthetic* unfolding of the previously discovered content in its more concrete necessary forms of realisation. From then on, the commodity ceases to be grasped in its exteriority as an 'inert' external object and the exposition starts to follow its self-movement as the subject of the development of those determinations previously discovered through analysis into ever more concrete forms. Crucially for our argument, the 'reproduction by means of thought' of value's necessary *form of appearance* as exchange-value, unfolds in *indissoluble unity* with the *content* of its determination as the reified representation of the immanent social character of individual private labours.

The synthetic exposition of the form of value or exchange-value thereby consists in the unfolding of the content of the value-determinations that had been brought to light through analysis but are now spoken 'in the language of commodities' (Marx 1976, 143). Yet, Marx's presentation does not start with the fully-developed monetary form in which all commodities effectively express their value, but with the *formal abstraction* consisting of the 'simplest value-relation […] of one commodity to another commodity of a different kind (it does not matter which one)'; what he names the 'simple, isolated, or accidental form of value' (139). Note, however, that regardless of whether one could see in the 'direct barter of products' a concrete empirical instantiation of this exchange relation between two different commodities, Marx's examination of the simple form of value is, at this particular juncture, entirely indifferent to any actually-existing pre-capitalist historical phenomenon. Rather, the object of his exposition is what is *formally* inscribed in the structure of the expression '20 yards of linen = 2 pounds sterling'. Moreover, we shall see that precisely for embodying the simplest expression of value of the commodity, this form bears the *essential qualitative determination* underlying the nature of *present-day*, *capitalist money*.

Marx makes two fundamental points from the examination of this form of value. First, value acquires an autonomous expression *vis-à-vis* the commodity which seeks to express its own value –called by Marx *the relative commodity*–, by being expressed or reflected in the physical body or use-value of the other commodity *–the equivalent* (Marx 1976, 141–42). Second, insofar as the two commodities that partake in the value-relation establish a 'relation of equality', they must be bearers of a common quality or substance. Having already uncovered the value-content through the dialectical analysis presented in the first two sections of chapter 1, his exposition can immediately point out that the common social substance residing in each commodity is the privately-performed socially necessary abstract labour congealed in them (143ff.). Thus, the qualitative content of the simple form of value already makes plain that at stake in the expression of value is the organisation of the private labours that comprise the total social labour. Marx stresses this point when considering the three peculiarities of the simple equivalent-form. These peculiarities indicate the way in which the 'internal antitheses' of the commodity – also already laid bare in the preceding analysis – become now expressed through the exchange relation in the mode of 'external antitheses'. More specifically, they show that the commodity acting as equivalent expresses, in the form of its opposite, the privately-undertaken socially necessary abstract labour that constitutes the substance of value.

In a nutshell, in showing how the use-value and the concrete private labour that produces the equivalent become socially recognised, or 'count', as the direct embodiment of, respectively, value and abstract social labour, the synthetic dialectical unfolding of the form of value brings to view, albeit in the mode of an inverted external reflection of its inner qualitative content, the general foundation of this historically-specific form of organisation of the intrinsically social life process of human beings. More concretely, by virtue of its indirect character, the material unity of the formally autonomous individual organs of social labour cannot be *consciously* established before the actual exertion of labour and on the basis of its concrete or useful character; instead, the validation of the social character of labour occurs 'behind the back of the producers', premised on the material expenditure of abstract or general labour and only once it has objectified in its product, in the ‘gelatinous’ form of the social attribute of general exchangeability.

Now, precisely for unfolding the social necessity for the value- or commodity-form of the products of private and independent labour, the simple form of value is defective to allow the commodity to adequately express that the labour that produced proved to be an effective component of social labour *as a whole*. In effect, the analysis of the ‘dual character of labour embodied in commodities’ contained in section 2 had already indicated that the commodity under scrutiny exists within a society in which the ‘qualitative difference between the useful forms of labour which are carried on independently and privately by individual producers develops into a complex system, a social division of labour’ (Marx 1976, 133). The exchange relation under examination in section 3 thereby is thus but a singular element of a social totality whose underlying *general unity* must be ascertained by means of commodity exchange. And this means that the indirect social relation that connects individual private labours through the exchange of their products must have a *universal* reach, which obviously is something that the simple form of value cannot accomplish when taken in isolation. As we have seen, the latter can mediate the explicit social recognition of the social character of labour represented by only two commodities. Consequently, in order fully to express value as what it is, i.e. the objectified representation of the privately-performed socially necessary abstract labour as the *general* social relation, any single commodity must relate to the whole ‘collection’ of them that comprises social wealth in the capitalist mode of production. This is the reason why Marx subsequently moves on to consider the ‘expanded’, ‘general’ and, lastly, ‘money’ forms of value, as the modes in which value progressively finds a suitable form of outwardly and tangibly expressing its ‘concealed’ social essence as the material representative of the general social character of individual private labours.

Note, however, that the properly *dialectical* unfolding of the movement of this *qualitative* determination is, in essence, already achieved with the simple form of value. The subsequent passage to the other, more developed forms of value is simply a formal movement that merely universalises the *quantitative scope* (and thus makes explicit) the qualitative content already expressed in the simple form (namely, the immanent necessity of value of acquiring an outward, differentiated mode of existence). In other, more polemic terms, the sequence of the more developed forms of value as such is not structured according to an immanent necessity of those forms, as some authors from the ‘New Dialectics’ current argue (Arthur 2004; Robles Báez 1997). As Iñigo Carrera (2013a, 58–59) puts it, the sequence of forms of value ‘does not imply a simpler form [of the exchange relation] engendering a more concrete one. Instead, the unfolding of the former’s necessity evidences the necessity of the existence of the latter’. This is, we think, the actual meaning behind Marx’s (1976, 139) remark that ‘the whole mystery of the form of value lies hidden in this simple form’. Seen in this light, the sequence of ‘defective’ forms of value should be re-signified as a succession of formal abstractions from a social process in which money already exists in its plenitude as the autonomous mode of existence of value common to the whole world of commodities.

At this juncture, it is worth stressing that Marx's exposition of the development of the 'forms of value' does not follow a 'historical order'; but neither does it follow a 'logical order' in Fine and Lapavitsas's sense. In our view, the gist of Marx's argument lies elsewhere. In a nutshell, the issue comes down to the fact that it is only the expression of value that progressively reveals the problem that the commodity-form of the product of labour is meant to solve. We are referring to the mediation in the establishment of the unity of social labour when performed in a private and independent manner. And since in this indirect form of social mediation of individual labours, the commodity that takes the form of general equivalent monopolises the form of direct exchangeability, the money-commodity becomes essentially determined as the objectified immediate embodiment of directly social labour in a society based on private and independent production.

Crucially for our argument, it should be noted at this point that Marx (1976, 139) insists that the 'simplest *expression* of value of a single commodity' is supplied by 'the *relation between the values* of two commodities' (emphasis added). In other words, the value-*expression* of any commodity is contained within the value-*relation* among them. It follows that the assumption of the social role of general equivalent-form by a certain use-value can only occur insofar as the latter was already able to enter the generalised exchange relation in the first place. But it can only do that insofar as it was determined as the product of private labour, i.e. as 'bearer of value' or as 'exchangeable social thing'. *This is the fundamental reason why money must necessarily be a commodity*.

In sum, such is the present-day determination of money as the independent form of value common to all commodities. Its discovery and explanation emerge out of an investigation that takes the individual *capitalist* commodity 'in our hands', analyses it to bring to view its hidden inner content and, finally, synthetically unfolds the immanent objectified social power which such content posits in the product of labour, and which is manifested in the exchange relation through the external 'doubling' of ordinary commodities and money. Consequently, and *pace* Ingham, it is a method which does not need to have recourse to historical analysis to prove or ground the essential social determination of money in the capitalist mode of production. On the other hand, and here *pace* Fine and Lapavitsas, insofar as we are dealing with the contemporary actuality of money, it is not possible to abstract from labour as the substance of value when considering the development of its necessary form of appearance as money. However, the reason for this does not lie, as Ingham (2006, 268) naively thinks through his eminently Ricardian reading of Marx, in an abstractly technical need to find an adequate 'unit of measurement'. As we have shown, the reason for this lies in the fact that in the capitalist mode of production, the organisation of all individual private labours that comprise the aggregate labour of society, attains its immanent social unity through the value- and money-forms.

In this sense, Marx's exposition in chapter 1 demonstrates that the production and exchange of commodities is the *general social relation* in capitalism. In other words, it is the *simplest*, hence *most fundamental*, form of social mediation through which, albeit in an *indirect* fashion, human beings organise their social life process. This has a key implication for the controversy over the nature and origin of money. For it means that in modern capitalist society all other non-mercantile social relations, such as the *direct* social relation of public authority that constitutes the state-form, must find its ultimate foundation and genesis in the concrete development of the determinations of the commodity-form (Blanke et al. 1976; Kicillof and Starosta 2007; Müller and Neusüss 1975; Starosta 2016, 218ff.). Thus, Marx's critique of political economy further undermines Ingham's attempt at grounding and explaining *capitalist* money (and, *a fortiori*, generalised commodity exchange), through direct relations of power and domination.

For its part, Lapavitsas response to Ingham fails not just because it adopts a logical-historical view of the genesis of money and, therefore, attempts to ground the present-day actuality of money in the course of history. In addition, it fails because in intending to find a concrete historical instantiation for each systematic 'moment' unfolded by Marx, he ends up explaining the genesis of money through the purposeful action and motives of commodity owners who exchange. Thus, he reads the exposition of the simple form of value as a 'logical analysis' of barter. By contrast, Marx's presentation of the form of value in chapter 1 not only dispenses with the course of history to explain the genesis of money but also with the conscious and voluntary action of 'exchangers'. As we shall soon see, the consideration of the latter is the immediate object of Marx's exposition in chapter *2* of *Capital*, which, as its title denotes, deals with the 'process of exchange'. In our view, this clearcut *form-determined* differentiation between the systematic treatment of the 'commodity' and that of the 'exchange process' was deliberately chosen and methodologically-informed. As a matter of fact, it stems from the discovery that the commodity and its immanent objective determinations constitute the *content* which is realised in and through the action of individuals in the process of exchange, who have become socially determined as *personifications* of alienated social powers that now belong to the product of their own labour. If, contrariwise, the immanent objective determinations of the commodity, on the one hand, and the purposeful action of exchangers, on the other, become conflated in the same systematic stage of dialectical development, the exposition cannot but overlook the respective order of determination that gives unity to the differentiated moments of the present-day general social relation in the flow of its essential *constitution* and more concrete *form of realisation*. This kind of conceptual collapse of different 'levels of abstraction', on which Lapavitsas evidently lapses, has been rightly criticised by various Marxist scholars (Arthur 2004, 37–38; Campbell 1997, 99; Heinrich 2012, 61–62; 2021, 132, 201; Lapatsioras and Milios 2012).

The precise and rigorous distinction between these different levels of abstraction that comprise Marx's dialectical exposition of the commodity and money are key not only to provide a consistent explanation of the commodity nature of money but also to grasp the specific part played by 'historical investigation' in his argument. Therefore, we shall now examine more closely the formal architecture of Marx's presentation which follows his discussion of the form of value, with particular focus on his exposition of the process of exchange.

The historical genesis of money

Having presented the constitution of the commodity as the general social relation through the examination of the 'form of value', and its producers as its *personifications* in section 4 on commodity-fetishism, Marx's exposition necessarily turns to the consideration of way in their purposeful action mediates the effective realisation of their thing-like social relation which they have *unconsciously* produced 'behind their own backs' (Starosta 2017). In effect, as chapter 2's opening line states, 'commodities cannot themselves go to the market and perform exchanges in their own right' (Marx 1976, 178). Therefore, commodity producers must now *personify value-relations in the process of exchange*. In other words, they must act as commodity *possessors*, who recognise each other in the juridical form of *private property owners*. However, Marx's closer scrutiny of the movement of the commodity-form of social relations as mediated through the conscious practice of commodity owners eventually reaches an apparent impasse: insofar as no *general* equivalent can emerge out of their intentional action, commodity owners prove to be unable to equate their products of labour as values. They seemingly turn out to be incapable of personifying the realisation of the alienated social powers of their commodities (179–80). The exposition resolves this apparent deadlock through the *immediate observation* of the effective action of commodity owners.

Indeed, Marx (1976, 180) concludes, in the personification of their alienated general social relation, commodity owners 'can only bring their commodities into relation as values […] by bringing them into relation with some one other commodity, which serves as the universal equivalent'. As Heinrich (2021, 196) has noted, in these brief lines at the opening of chapter 2, Marx is implicitly polemicising with 'contractual theories' which 'see money as essentially the result of a common insight on the part of those engaged in exchange'. In stark contrast to these theories, Marx shows that money *cannot* result from the voluntary action of exchangers. In this sense, in these passages neither is Marx positing 'money as a resolution for the problems of direct exchange', as Fine and Lapavitsas (2000, 380n7) claim, and as is implicitly suggested by Ingham's identification of Marx's argument with that of neoclassical economics. As a matter of fact, Marx's argument is precisely the opposite: he actually shows the impossibility of explaining money in those terms!

Still, the case against the idea that money arises out of social convention does not boil down, as Heinrich (2021, 197) submits, to the observation that 'money […] is the result of a *contemporary* social process, in which we all participate when buying or selling, that is repeated again and again'. Certainly, the practical action of commodity owners 'instinctively' reproduces, on a daily basis, the existence of money. However, this *re*production can only take place because money has already been *produced* at some point. Otherwise, the argument would lapse into the aforementioned impasse faced by the analysis of the conscious and voluntary action of commodity owners: the latter cannot engender a general equivalent. Thus, the actual corollary of Marx's exposition at this juncture is that what is now in need of an explanation is the 'action of society' that 'turn[s] a particular commodity into the universal equivalent' (Marx 1976, 180). Therefore, the question whose explanation is still pending is the 'social action of all other commodities' which 'sets apart the particular commodity in which they all represent their values' (180). In other words, what needs to be explained is the *original production of money*. But this cannot be accounted for by the contemporary action of commodity owners. In effect, such a social process stands in absolute opposition with the general form taken by the consciousness of these individuals: insofar as they are socially determined as free and equal subjects, no commodity owner will cede to another – nor can they arrogate to themselves – the social power to monopolise the use-value which embodies the form of direct exchangeability, i.e. the immediate possibility of being unconditionally recognised as an effective individual organ of social labour.[4]

This is the reason why Marx's (1976, 181) exposition subsequently turns to the examination of the '*historical* broadening and deepening of the phenomenon of exchange' which explains how 'a particular commodity is transformed into money' (emphasis added). Put differently, at this juncture, Marx momentarily brackets the consideration of the present movement in which the general social relation unfolds and turns to the examination of the determinations that the latter carries within itself as *result of its historical becoming*. In a nutshell, Marx's (1973, 460) dialectical presentation reaches the point 'where historical investigation must enter in'. This change of course experienced by the Marxian exposition a couple of pages into chapter 2 has been scarcely discussed by the specialised literature. As we have seen, most scholars working on Marx's method tend to reduce all allusions to historical processes in *Capital* to a mere 'illustration' of the pure systematic development of capitalist social relations or, at most, they boil the role of 'historical investigation' down to the explanation of 'primitive accumulation', which would thereby allow the explanation of the 'transition between modes of production'. In this sense, Heinrich's contribution stands out for at least acknowledging that Marx's exposition in chapter 2 deals with 'the *historical* development of money in pre-capitalist conditions' (Heinrich 2021, 199) and, above all, for discussing the historical course of the genesis of money in methodological terms. However, we have already suggested that Heinrich considers that it suffices to consider the role of the present-day action of commodity producers in the reproduction of the general equivalent in order fully to account for the existence of the process of exchange and, *a fortiori*, for that of capitalist money itself. Against this backdrop, he provides no grounds for the methodological significance that the inclusion in this instance of a *historical* investigation of the evolution of the 'phenomenon of exchange' could have for Marx's *systematic* explanation of the *contemporary* determinations of money.

By contrast, we think that the examination of the historical development of money is as key to the explanation of this contemporary existence as the systematic unfolding of the 'form of value'. More polemically put, in the same vein as Marx does not unfold a systematic development of the immanent determinations of money which is paralleled by their historical emergence and evolution, as argued by Engels and those who follow his 'logical-historical' method, he does not develop two *separate* dialectics, one systematic and one historical, as 'New Dialecticians' believe. In our view, what Marx does is to systematically develop the immanent necessity of a determinate contemporary social form (i.e. generalised commodity production), up to the point where that very same systematic development places him before the need to account for the pre-capitalist historical genesis and evolution of the social form under scrutiny, and which has coalesced in its present-day mode of existence.

Against this backdrop, let us now see which is, according to Marx, the general course undergone by the said historical genesis of money. Insofar as the systematic development of the determinations of capital has yet to show the historically-specific role of capitalism in the development of the productive forces of social labour, the analysis of the historical genesis of money proceeds in abstraction from the more concrete mediating forms through which this process unfolds. In other words, the exposition of the historical process is done in an overly 'schematic' manner, with what might appear as a one-sided focus on the evolution of commodities and money without regard to the broader social forms in which they originally emerged and developed. Still, this 'stylised' historical account suffices to throw into relief that present-day money has emerged as the product of a 'social act' which predates the action of capitalist commodity owners. Moreover, this means that this social act which brings money into existence in the first place, i.e. the *original production* of money, must follow a course which is exactly the *opposite* to that which *reproduces* its existence within capitalism. In effect, if Marx's systematic development had earlier shown that money *cannot* crystallise out of the action of free private individuals whose exclusive *indirect* general social nexus is the commodity, its historical genesis now shows that money has been engendered through the action of individuals who are subject to *direct social relations of personal dependence*. Here we have a clear instance of the previously cited methodological remark by Marx (1973, 107–8) that the sequence of 'economic categories […] determined […] by their relation to one another in modern bourgeois society […] is precisely the opposite of that which seems to be their natural order or which corresponds to historical development'. But this is not the only instance.

Insofar as development of money derives from the determinations of the commodity, Marx (1976, 181) tracks down its genesis to the first historical manifestations of the exchange process in the form of the 'direct exchange of products'. In these germinal expressions, the products of labour 'are not as yet commodities, but become so only through the act of exchange' (181). In other words, rather than being a *presupposition or premise* of the act of exchange, the constitution of the commodity-form is its *result*. Similarly, a useful article is turned into an 'exchangeable object' through the consciousness and will of its possessor, rather than their conscious and voluntary action being the personification of the fetishised attribute of exchangeability residing in the object. Lastly, these commodity possessors relate in exchange as independent producers only insofar they 'agree tacitly to treat each other as the private owners of those alienable things, and, precisely for that reason, as persons who are independent of each other' (182), instead of being already determined as autonomous commodity producers from the very outset and, on that basis, further relating in the exchange process in the juridical form of private property owners.

On the other hand, the first monetary forms emerge as soon as exchange expands and turns into a 'normal social process' and, therefore, in the face of the need for 'the articles exchanged' to 'acquire a value-form independent of their own use-value, or of the individual needs of exchangers' (Marx 1976, 182). In these circumstances, the social necessity for an independent mode of existence of value is also constituted by virtue of a determination which is 'precisely the opposite' of that which is the foundation of the money-form under capitalist commodity exchange. In the former, money develops as a way of resolving the practical limits that the direct barter of products imposes upon the scope and scale of the exchange process. Conversely, in the latter money develops as the necessary form of manifestation of privately-undertaken socially necessary abstract labour materialised in commodities. In other words, whereas in its historical origins money essentially emerges in its function as 'means of circulation', as an 'inner moment' of capitalist society its primordial function is to be the 'material embodiment of human labour as such' (183) – hence to act as the external measure of the immanent measure of value of commodities.

Seen in this light, it should now be clear the error involved in any attempt to equate the factual chronological sequence entailed by the historical origin and evolution of a certain social phenomenon, with the order in which the different determinations of its constitution 'relate to one another in modern bourgeois society'. Thus, Lapavitsas's reading of Marx's development of the 'form of value' in section 3 of chapter 1 as a historical development makes no sense. In effect, the 'interstitial' commodity which emerges out of the direct exchange of products between foreign human communities is not constituted as such as a *premise* of the exchange process. Consequently, it does not bear an immanent 'purely social objectivity' which needs to acquire an external mode of existence in a general equivalent. For their part, 'primitive' exchangers are not free individuals whose sole social tie is the product of their own private and independent labour. It thereby follows that the formal problem entailed by the personification of value-relations in the exchange process when the commodity has become the general social relation has no relevance when analysing the historical genesis of money. In the same vein, Ingham's attempt to explain the contemporary actuality of money on the grounds of its historical origin is also futile. As we have just seen, in the historical course of events the present determinations of money appear in an inverted manner. And this applies not only to the order of determination between direct and indirect social relations or to the sequence of emergence of the different functions of money but also, as Arthur (1996, 196) sharply notes, even to the very concrete forms in which those monetary functions are actualised.

Conclusion

In this chapter, we have looked into the essential nature of money and its more general or simpler determinations in a methodologically-minded manner. To do so, we first addressed the issue through a critical engagement with the debate between Ingham and Lapavitsas. The former attempts to offer 'sociological' foundations to the post-Keynesian theory of money. In essence, this approach sees money as a conventional unit of account established by the public authority with the purpose of homogenising and measuring all credit obligations, which is what all monetary phenomena boil down to according to this view. For his part, Lapavitsas (together with Fine), aims at the defence of the Marxian perspective based on the commodity nature of money and, *a fortiori*, on the genesis of money in the exchange process.

Leaving aside all substantive considerations about each of these stances on the nature and genesis of money, the first conclusion that can be drawn from our critical examination of the polemic is primordially methodological. In our view, the dispute between these scholars and, in particular, Lapavitsas's failed attempt at a convincing Marxian response to Ingham's criticisms, strikingly lay bare the pitfalls of the so-called 'logical-historical' method for the development of the critique of political economy. As we hope to have shown in this chapter, the explanation of the commodity origin and essential character of present-day capitalist money and its further determinations must be fundamentally provided in systematic-dialectical terms.

On the other hand, we have also argued that this mode of investigation proves to be insufficient fully to explain the most abstract or general determinations of contemporary money in their unity. On this score, our approach parted company with many recent contributions on the method of the critique of political economy broadly identified with the so-called 'New Dialectics'. In effect, we have seen that it is through the unfolding of the general determinations of money from the standpoint of the process of exchange –i.e. the object of Marx's exposition in chapter 2 of *Capital*– that the pure systematic presentation reaches the first of the few instances in which the dialectical method places us before the need circumstantially to turn to a historical mode of investigation. Moreover, we have thrown into relief that those passages exhibit, in a particularly eloquent fashion, another aspect of Marx's dialectical method that he emphasised in his occasional methodological remarks scattered throughout his works, namely: that the systematic sequence of 'economic categories' and their immanent determinations usually inverts the order in which they have developed in the course of history. As should be obvious, this issue does not entail a merely scholastic exegetical interest but is of immediate relevance for the comprehension of the genesis and essential character of contemporary capitalist money.

The second conclusion that can be drawn from our discussion is of a more substantive character, although we shall see that it does entail methodological ramifications. We have argued that money must necessarily be a commodity and, moreover, that it is engendered in the exchange relation between commodities which mediates the expression of value in the form of exchange-value – and which in turn mediates, in a reified form, the indirect establishment of the unity of the privately-undertaken social labour. As a matter of fact, both points are two sides of the same coin: only for being a commodity – i.e. for possessing the attribute of exchangeability as the purely social representation of the materialisation of the privately-organised socially necessary abstract labour – can a particular 'thing' enter that relation in the first place and, as a consequence, serve as the general equivalent common to the rest of them. This is the main reason why the essential simplest determination of money cannot be reduced to a mere unit of account of ‘abstract value’, as Ingham submits. But neither can it boil down to a contentless formal monopoly of the ‘ability to buy’, as posited by Lapavitsas. Rather, we have argued that the essential form-determination or ‘function’ of money consists of being the materialised or objectified embodiment of the social character of private labour. In turn, as just emphasised, we showed that it can only perform that role solely in its own capacity as such product of this historically-specific form of organisation of the immanent general unity of social labour.

In this sense, as Germer (1997, 53) convincingly suggests, the Marxian claim that money is a commodity is not grounded in the immediate observation of an empirical phenomenon, such as the prevalence of the ‘gold standard’ in Marx’s times. It thus follows that the substitution of diverse forms of credit money for the money-commodity in the function of means of circulation and means of payment or, more recently, the existence of a standard of prices which since 1971 have broken any explicit legal-institutional link with quantities of the money-commodity, do not represent sufficient grounds for rejecting the Marxian view of the commodity nature of money (50–52).[5] Note, however, that this is not simply a question of unavailability of conclusive empirical evidence, as supporters of a Marxist theory of pure credit-money admit (Foley 2005, 47). The fundamental question is, again, *methodological*. More concretely, we have argued that the most general ground for the commodity nature of money is not historical but systematic. And this necessarily means that such an abstract or simple determination of contemporary money must be carried over as the immanent, objectively-real content of whichever more concrete modes of existence it may assume. In other words, this simplest determination of money still constitutes its most general content even if it appears *in the mode of being denied* in its more concrete forms of realisation. Thus, whether one wanted to ‘critique’ or ‘defend’ the Marxian perspective on the commodity nature of money, this could be consistently approached only through a thorough re-examination of the more abstract or general determinations of money as presented by Marx in the opening chapters of *Capital*. This is what we have attempted to do in this chapter, albeit through a critical engagement with the controversy between Lapavitsas and Ingham, whose merit precisely resides in referring the question back to the general foundations of money.

Admittedly, all this still begs the question of the internal connection between those simpler immanent determinations of money and the concrete forms taken by the contemporary configuration of the ‘monetary system’. It goes without saying that a proper discussion of this issue exceeds the scope of this chapter. However, a couple of pointers can be provided in the remaining concluding remarks. First, that the said unity between the more general content of money as a commodity and its more developed forms of existence can only be uncovered by the systematic unfolding of all the sequence of mediations through which the self-negating movement of the money-commodity is realised, up to the point of accounting for its contemporary figures. Secondly, that the seeming ‘absolute autonomisation’ of the various functions of money *vis-à-vis* the money-commodity have their basis in the longstanding crisis of overproduction which the world economy has been experiencing since the 1970s, and whose full resolution has been recurringly postponed by means of successive waves of credit-fuelled expansion (Iñigo Carrera 2013b, 208ff.). Hence also the *limits* to that appearance of complete abolition of the commodity nature of money. In effect, as Marx forcefully points out in Volume III of *Capital*, those limits will most likely assert themselves one way or another with the overt manifestation of the general accumulation crisis, which actually constitutes the phase of the cycle in which the immanent social unity of the privately- and independently-organised material reproduction process, becomes externally re-established in the most violent manner.

Notes

1 For a concise presentation of the main tenets of this methodological current, see Kincaid (2009).

2 At the level of textual evidence, it is admittedly true that in the section on 'the value-form or exchange-value', Marx (1976, 158) notes that the first and second forms of value 'appear in practice' or 'come into actual existence' in historical stages that predate capitalism. However, even a cursory reading of that section suffices to see that this sort of parallelism between the unfolding of the present-day sequence of form-determinations and the historical course of phenomena has a merely *incidental* character within the overall architecture of Marx's systematic-dialectical presentation. In this sense, as Iñigo Carrera (2021, 98) points out, it is sensible to grasp those remarks as 'interjected in an external manner *vis-à-vis* the proper course of dialectical cognition which Marx's exposition has been unfolding up to that point'. In addition, as Heinrich (2021, 129) appropriately comments, 'Marx makes these remarks only after analyzing the forms. Therefore his analysis of the forms is in no way based on a historical development'.

3 A similar proposal for the postponement of the introduction of labour as the substance of value can be found in other authors writing from different methodological traditions like Arthur (2004) and Campbell (2013) from the 'New Dialectics' or Reichelt (2007) from the *'Neue Marx-Lektüre'*.

4 In contrast to Heinrich, Campbell (2004, 67–77) perceptively notices the impossibility of explaining the 'original crystallisation' of money based on the contemporary action of commodity owners. Moreover, she rightly justifies the need to introduce the historical development of the genesis of money precisely by virtue of the inability of the present-day movement of the general social relation to set apart a particular commodity as the general equivalent. However, she falls short of drawing the general methodological implications of this particular instance of the Marxian presentation for the thematisation of the nexus between systematic development and historical investigation in materialist dialectical thought. Moreover, she fails to show the relevance of the introduction of the historical sequence of social phenomena in the exposition, to throw into relief the inversion experienced by such an order of determination *vis-à-vis* that of their systematic unfolding as inner 'moments' of the present-day social totality.

5 For a concise discussion of the development of a 'dollar standard' after the collapse of Bretton Woods, see De Brunhoff (2005).

4 Skilled labour and value-production

An alternative approach to a longstanding and unresolved controversy in the critique of political economy

Introduction

The degree of complexity of the different kinds of labour is one of the fundamental obstacles faced by any sound explanation of prices grounded in the quantity of labour materialised in commodities. As Adam Smith (1982, 134) already noted in the *Wealth of Nations*, it is evident that 'there may be more labour […] in an hour's application to a trade which it cost ten years' labour to learn, than in a month's industry at an ordinary and obvious employment'. As we will see, Marx's solution to this problem is extremely concise and, at first sight, very simple. Essentially, he considers the expenditure of labour-power that involves a prior 'certain level of development' as '*intensified*, or rather *multiplied* simple labour, so that a smaller quantity of complex labour is considered equal to a larger quantity of simple labour' (Marx 1976a, 135). Yet, a century and a half after the publication of *Capital*, Marxists have not reached any consensus on the 'skilled labour reduction problem' or, worse still, even on what Marx actually meant in those brief passages.

Against the backdrop of these debates, the purpose of this chapter is, on the one hand, to undertake a critical reconstruction of the history of the controversies over the Marxian solution to the 'skilled labour problem' and, on the other, to present an alternative perspective which is consistent with the foundations of the critique of political economy. In order to do so, in the following section, we offer a brief overview of Marx's textual legacy on this issue. The next two sections develop a reconstruction and critical examination of the debates that followed the publication of *Capital*. In the fifth section, we turn to the presentation of our own alternative solution grounded in the Marxian analysis of the determinations of the commodity-form. Finally, the concluding section brings together the main results of our discussion.

Marx on skilled labour

Marx made very few and rather succinct references in his works to the question of skilled labour in connection with the determination of value. Moreover, the occasional remarks that one can find in his writings are mostly incidental, that is, external to the systematic structure of his exposition. As acknowledged by most

DOI: 10.4324/9781003201939-5

exegetical commentaries, the upshot of this is that the reconstruction of Marx's ideas on this subject is not free from difficulties (Cayatte 1984; Krätke 1997). However, we think that it is possible to uncover a mostly unchanged view underlying and unifying all these scattered references to skilled labour that Marx made throughout his writings. On the basis of a close reading of available textual evidence, in the following points, we summarise its most salient features:

I It is crystal clear that Marx thought that the determination of human labour as the substance of value implies the reduction of those qualitative differences in the diverse types of labour, derived from the special development of the labour-power of which they are an expenditure, to a 'common unit'. It follows that the explicit treatment of this reduction, therefore, pertains to the level of abstraction of the simplest determinations of value. Furthermore, this implies that as long as there are labours of varying degrees of complexity, the 'reduction problem' persists and cannot be assumed away (Marx 1872, 17; 1973, 561, 613, 846; 1976a, 135, 275–76; 1976b, 126–27; 1985, 122; 1987, 272–73; 1989a, 322). However, it is also evident that insofar as Marx regarded it as a relatively 'minor' and unproblematic issue, it was not primordial to unfold the 'laws' that govern the reduction when the immediate object of the exposition was the commodity or the value-form of the product of labour.

II The aforementioned 'common unit' is simple labour, which is defined as the expenditure of human labour-power possessed by the 'average individual', for which no prior 'special development' of productive attributes is needed (Marx 1872, 17; 1973, 323–24, 612–13, 846; 1976a, 135; 1976b, 126–27; 1985, 122; 1987, 272–73). Although what constitutes simple labour varies according to the different 'epochs of civilisation' and in 'different countries', it is always given in a determinate society (Marx 1872, 17; 1976a, 135; 1987, 272–73).

III Marx is adamant that the equivalence entailed by the 'value-objectivity' immanent in commodities self-evidently shows that the reduction of complex to simple labour is 'accomplished in practice' and, like all other reductions of qualitative differences in the varied commodity-producing labours, it operates 'behind the backs' of the producers (Marx 1872, 17; 1973, 612–13, 846; 1976a, 135; 1976b, 126–27; 1987, 272–73).

IV Moving to the level of abstraction of the capital relation, Marx argues that labour-power of a greater degree of complexity has a higher magnitude of value because its production costs more socially necessary labour (Marx 1973, 323–24; 1976c, 1032; 1988, 48). However, in other passages, he does not only make that point but also invariantly remarks that skilled labourers proportionally produce the same amount of surplus value as simple labourers. In other words, the rate of surplus value is the same for all kinds of workers, regardless of the relative complexity of their labour-power (1976a, 304–6; Marx 1988, 81–82, 90, 231; 1989a, 18; 1989b, 72–73; 1991a, 241; 1991b, 309; 2015, 250). In this context, Marx sometimes appears to be suggesting that there is some sort of connection between the value of skilled labour-power and the value of its product.

V Still, Marx tended to believe that simple labour constitutes the great bulk of labour performed in any society and that, at any rate, there was a dynamic tendency immanent in capitalist forms of technical change gradually leading to the elimination of complex forms of labour (Marx 1973, 612–13; 1976a, 470; 1976b, 127; 1976c, 1032; 1977, 225; 1987, 272–73; 1988, 231, 321, 331, 341; 1991a, 298; 1991b, 484ff., 499; 1994, 24, 148, 217; 2015, 306).

VI Finally, it seems to us that Marx did not consider that Ricardo's treatment of the subject was quite simply 'wrong'. In our view, he thought that it was rather 'incomplete', insofar as Ricardo did not show how the relation between complex and simple labour is actually 'determined' (Marx 1973, 561; 1976b, 127ff.; 1986, 327; 1989a, 350).

Now, as Krätke notes, there are other references to 'complex labour' in Marx's writings. However, these are usually *analogies* which Marx uses in order to shed light on *other* determinations of value-production and/or realisation (Krätke 1997, 102–3). Thus, for instance, Marx (1989a, 440) points out that when in a special sphere of production the *intensity* of labour is circumstantially higher, it counts socially as if it were more complex labour. Similarly, when an individual capital sets into motion a comparatively higher productivity of labour than its competitors, this circumstance is reflected in the value of its output as if it were the product of more complex labour (Marx 1976a, 435, 530; 1988, 319–20, 329–30). Lastly, Marx (1988, 338; 1989a, 294) also uses the determinations of the multiplied value-positing powers of complex labour to explain by analogy the determinations of *international* value-relations when the low degree of capital mobility hinders the full operation of the 'law of value' on a world scale.

Two general conclusions can be drawn from this reconstruction of Marx's thinking on the determinations of skilled labour in relation to value-production. In the first place, the problem itself seemed to be of relatively minor relevance for Marx's own explanation of the value of commodities. Moreover, at least as far as its simplest aspects are concerned, he tended to think that classical political economy (Ricardo in particular) had already offered the basic elements for the solution: working days of different complexities are equalised as 'multiples' of simple labour. In the second place, despite his repeated criticisms of Ricardo for not 'developing further' those elementary aspects of the solution, in no text does Marx himself actually complete the explanation. This would have involved the establishment of the principle that allows to explain, in a rigorous and precise fashion, the specific reasons why complex labour posits more value than simple labour during the same time. But this full explanation is not only missing in Ricardo's text; unfortunately, it is also absent from Marx's own works. What is more, when one considers that according to Marx himself (1985, 123) the explanation of the value of commodities 'is, therefore, a thing quite different from the tautological method of determining the values of commodities by the value of labour[-power], or by *wages*', the references that explicitly or implicitly correlate the higher wages of skilled labourers with the higher value of their product are intriguing to say the least. In sum, Marx's own explanation of the multiplied value-producing powers of skilled labour is admittedly as underdeveloped as that of his predecessors and deserves closer critical scrutiny. Before doing that, we shall first examine the reactions that this aspect of the Marxian critique of political economy caused among both his critics and his followers.

The critiques of Marx's perspective on the 'reduction problem' and the response of Marxists

The critique of the Marxian solution

The fundamental two lines of criticism of Marx's 'solution' can be found in the work of Böhm-Bawerk. In his 1884 *Capital and Interest*, this author initially pointed to what he considered an elementary flaw in Marx's value theory. According to Böhm-Bawerk (1890, 384–85), there was no clear explanation of the sense in which a complex labour's working day could be said to 'condense' *more labour* than an equally-long working day of simple labour. Thus, in Böhm-Bawerk's view, that the product of a complex labour's working day represents a higher amount of value than that of simple labour blatantly contradicts the economic law that postulates that value is determined by the amount of labour objectified in commodities. Consequently, Böhm-Bawerk concluded, the products of complex labour can only be (yet another) exception to the general rule in the Marxian explanation of value.[1]

The second main line of Böhm-Bawerk's criticism appeared in his intervention in the debate triggered by the publication of Volume III of *Capital*. More specifically, in *Karl Marx the Close of His System* (Böhm-Bawerk 1949), he further maintained that the Marxian explanation of the equalisation of qualitatively different labours fails because the argument unfolds 'in a complete circle': it starts out in search of an explanation of the exchange relation but, insofar as it is argued that 'the standard of reduction [of skilled to simple labour] is determined solely *by the actual exchange relations themselves*' (83), it ends up accounting for the exchange relation… on the basis of that very same exchange relation!

Later critiques of Marx mostly reiterated or simply reformulated the foundational ideas already laid out by Böhm-Bawerk (Bortkiewicz 1952, 90–92; Joseph 1923, 87–96; Masaryk 1899, 270ff.; Mises 1990, 20–21; Skelton 1911, 117ff.; Sorel 1897, 230). Those that did bring novel issues to light actually changed the very terms of the discussion, focusing on the difference between 'innate' and 'acquired' qualifications rather than on complex labour and simple labour as such. For instance, this is the case of Oppenheimer's (1916, 63–64) objections. Subsequently, this angle on the question reappeared in the works of both Schumpeter (2006, 24n3) and Samuelson (1971, 404–5), for whom Marx failed to explain the 'natural' differences in the quality of labour.

The 'rise and fall' of the classic Hilferding–Bauer response

With the exception of a brief and rather inconsequential rejoinder to Block by Lafargue (1884, 283–84), the first spate of responses to Böhm-Bawerk's criticisms did not come from Marxists but from Ricardians (Dietzel 1895, 248–61) or non-Marxist socialists (Grabski 1895). In a nutshell, the essential point made in these first interventions to counter Böhm-Bawerk's objections anticipated the gist of what some years later would constitute the 'canonical Hilferding-Bauer' response by Marxists. Specifically, these works submitted that the reduction of complex to simple labour involved the addition, to the living labour of the skilled labourer, of *all* those past labours that had directly or indirectly contributed to the production of the productive attributes of the worker bearing a more complex labour-power.

Still, the actual first reply by a Marxist came from Bernstein and was along rather different lines. According to Bernstein, the greater value of the product of skilled labour was not explained by the exchange relation, as Böhm-Bawerk's had thought, but by the greater value of more complex labour-power. Thus, the higher the value of labour-power, the greater will be the magnitude of value that results from its objectification (Bernstein 1899, 359–60).[2] Bernstein's idiosyncratic solution did not, however, persuade all Marxists. Indeed, the first critical reaction almost immediately appeared in the work of Kautsky (1899, 41), who saw Bernstein's solution as 'eclectic'. Although he acknowledged that Marx's theory was 'incomplete' on this score (38–39), Kautsky offered no solution of his own.

An alternative Marxist approach to the 'reduction problem' eventually emerged some five years later, by other scholars who took Bernstein's explanation to task for relapsing into a theory of value founded on 'costs of production'. This was the main thrust of Hilferding's criticism of Bernstein in his rejoinder to Böhm-Bawerk's 1896 article. As Hilferding (1949, 141) puts it, Bernstein's explanation wanted 'to deduce the value of the product from the "value of labor"'.[3] By contrast, Hilferding and other authors proposed a procedure for the reduction of skilled to simple labour based on the addition of the quantities of simple labour that materialised in the production of skilled labour-power and which, indirectly, become 'condensed' in the actual expenditure of the latter. Those past formative labours, Hilferding states, 'are stored up in the person of the qualified laborer, and not until he begins to work are these formative labors made fluid on behalf of society'. Specifically in Hilferding's case, these 'formative labours' came down to the work of the 'technical educator' (144). However, drawing on Deutsch (1904), Bauer (1906, 649ff.) later argued that the labour of 'self-education' by the skilled labourer themselves (in their capacity as student) should also be counted.[4]

Thus, the 'classic' Marxist view of the 'reduction problem' crystallised out of these contributions from the beginning of the 20th century. In a nutshell, this 'Hilferding–Bauer' solution maintained that the higher value-positing powers of complex living labour derived from its 'condensation' of *all* past labours which have been expended in the production of the respective skills of the wage-labourer, including both that of the 'technical educator' and that of the 'student'. During the greatest part of the 20th century, the Hilferding–Bauer approach was widely accepted by Marxists of the most varied traditions as the definitive response to Böhm-Bawerk (Hodges 1961; I. Lapidus and Ostrovitianov 1929, 32–35; Mandel 1976, 72–73; Meek 1973, 168ff.; Rosdolsky 1977, 506ff.; Rowthorn 1974; Rubin

1972, 159ff.; Sweezy 1970, 42–43).[5] Moreover, this 'classic' solution tended to be endorsed not only by most Marxists but also by Neo-Ricardians scholars (Bródy 1970, 86–88; Okishio 1963; Roncaglia 1974).[6]

However, by the mid-1970s, some Marxists started to raise some reservations against the alleged solution to the 'reduction problem'. In the first place, it was argued that the Hilferding–Bauer reduction procedure implied different rates of surplus value for skilled and simple labour which, it was claimed, contradicted the Marxist theory of exploitation (Morishima 1973, 193; Morris and Lewis 1973, 457–58). Secondly, other scholars argued that in conceiving of the worker's skills as the material condensation of past labour that would subsequently be represented in the higher value of the product, the productive attributes of workers were treated as constant capital (Bidet 2007, 26; D. Harvey 2006, 58; Tortajada 1977).[7] According to this second line of criticism, the 'classic' solution entailed a serious relapse into 'human capital' theory, which had been explicitly developed to undermine the Marxist theory by denying the existence of antagonistic social classes (Tortajada 1977, 109). In sum, these critics concluded, the Hilferding–Bauer solution had to be abandoned.

The more recent proliferation of novel solutions to the 'reduction problem'

In the face of the shortcomings of the traditional reduction procedure, new alternative approaches appeared that changed considerably the very terms of the problem without, however, achieving any consensus. Let us briefly consider these more recent perspectives on the reduction of complex to simple labour in turn.

In the first place, some scholars proposed that the reduction of skilled to simple labour should be regarded as a *real and observable process of de-skilling of labour-power resulting from capital's transformation of the labour process* (Carchedi 1991, 130–34; D. Harvey 2006, 57–61; Itoh 1987; Kay 1976; Sekine 1997, 39; 2020, 193–96, 205–6, 558; Uno 1977, 32n2).[8] From this standpoint, the solution to the reduction problem does not belong in the simplest level of abstraction of the commodity-form but pertains to a dynamic tendency of the production process subsumed under capital, namely: the actual homogenisation of the productive attributes of all wage-workers resulting from the forms of technical change in the capitalist mode of production. As a result of this historical process, these authors conclude 'the reduction problem disappears into insignificance' (D. Harvey 2006, 61).

In the second place, some authors have argued that the key to the solution resides in treating more complex labour as more *productive* (Bidet 2007, 20–21; P. Harvey 1985; Saad-Filho 1997; 2002, 56–58).[9] Note that insofar as this refers to an augmented capacity to produce *use-values* per unit of time, this kind of approach must offer an explanation of how this greater *physical productivity* of skilled labour translates into multiplied *value*-producing powers. Here each author provides their own, highly idiosyncratic argument. Thus, P. Harvey simply *assumes axiomatically* that skilled labour *is* 'labour-saving' (that is, physically more productive), and extends this assumption to *more intensive* labour, further postulating that the latter's greater value-creating capacities are grounded in its higher physical productivity

(P. Harvey 1985, 90). By analogy to labour intensity, he thereby explains the multiplied value-creating power of skilled labour. For his part, Bidet claims that since commodity- and value-production is actually the fruit of *collective* labour, it makes no sense to assign differential value-creating powers to certain individual types of labour-power.[10] However, he also maintains that the incidence of what he calls 'specialised' labour-power in a determinate collective labourer does improve its overall productivity. And through a peculiar interpretation of Marx's argument on the individual capital's production of an extra surplus value from innovation in chapter 12 of *Capital* Volume I, he concludes that the higher productivity resulting from a greater level of 'specialisation' in a collective labourer is expressed in greater value-production per unit of time (Bidet 2007, 29–30).[11]

Finally, there has been a number of rather disparate singular attempts at a solution which cannot be lumped together into any discernible common approach (Devine 1989; Ekeland 2007; Himmelweit 1984; Shaikh and Glenn 2018). Among them, the one by Himmelweit stands out for the critical reactions that it provoked among other Marxists (Fine 1998, 191ff.; Itoh 1987; Lee 1990, 117ff.; Morris 1985). In a nutshell, Himmelweit (1984, 335) argues that, under the assumption of equal organic compositions of capital, the mobility of capital in the process of equalisation of the rate of profit ensures the corresponding equalisation of the different rates of surplus value, so that 'if one group of workers are employed at a higher rate of pay than another, they will also produce more value'. Also, mention is worth making of Shaikh and Glenn's recent attempt at a mathematical formalisation, which allegedly avoids the shortcomings of traditional approaches through a reduction coefficient based on an exponential function that allows the computation of 'cost skilling'. According to these authors, this allows the representation of more complex labour properly as value-producing, unlike 'the traditional additive form that only transfers value and does not create value' (Shaikh and Glenn 2018, 19).

Critical assessment of the complex labour debate

Let us now take stock of the discussion so far through a closer critical examination of the debate on complex labour that we have just sketched out in the previous section. As already mentioned, Böhm-Bawerk's main objection to Marx's argument in *Capital* focuses on the circularity involved in maintaining that 'experience shows' that 'value' and the 'social process' (which Böhm-Bawerk equates with 'exchange') accomplish the reduction, while simultaneously presupposing the reduction to explain the exchange relation itself. But this is not the only objection. Additionally, Böhm-Bawerk (1949, 82) accuses Marx of explaining away the irreducible qualitative difference between two 'different *kinds of labor* in *different amounts*' by resorting to a scientifically flawed procedure consisting in the substitution of 'to count as' for 'to be' in the consideration of skilled labour as multiplied unskilled labour. According to Böhm-Bawerk, this train of thought is theoretically illegitimate since 'to "count as" is not "to be", and the theory deals with the being of things' (82).

Now, a proper full response to these further two objections would require a wider discussion of Böhm-Bawerk's more general critique of Marx's value theory, a task which evidently exceeds the narrower scope of this chapter on the skilled labour reduction problem and which, moreover, we have undertaken elsewhere (Starosta 2008; 2016, 119ff.). Here we can only offer a few pointers on the underlying weakness of Böhm-Bawerk's critique. In a nutshell, the issue comes down to Böhm-Bawerk's failure to grasp the fetish-like character of the 'value-objectivity' that constitutes the essential 'form-determination' that stamps the product of labour as a generally-exchangeable thing and hence as a commodity (Starosta 2017). In other words, Böhm-Bawerk overlooks that, as the *historically-specific* property of *general exchangeability*, value is an objective attribute which is *immanent* in the commodity and which is distinguishable from both exchange-value, which is its necessary form of appearance, and (privately-performed socially necessary) abstract labour, which constitutes its substance. By contrast, as Elson (1979, 157) notes, in his (mis)reading of Marx's argument, Böhm-Bawerk *unmediately* passes over from the exchange relation to labour. Relatedly, he misses the crucial point that Marx is not analysing the commodity 'in general', but a *capitalist* commodity, that is, one existing in a society in which commodity production has become the *general* social relation and whose exchange, therefore, does involve *equivalence* (hence *qualitative identity* and *quantitative necessity*) (Arthur 1979, 71). Thus, he fails to understand that it is the purely social, yet practically real, reified objectivity of value that makes different commodities 'count as' qualitatively identical and which, consequently, negates in practice all qualitative differences intrinsic to the materiality of the varied kinds of labours that produced them. Therefore, it is this historically-specific form of the social life process that 'reduces' individual products of labour to their most general remaining common determination, namely: that of being materialisations of abstract, socially necessary simple labour (Starosta 2016, 141ff.). In other words, the actual 'proof' that the reduction of complex to simple labour does take place is synonymous with the exposition of the determinations underlying the social constitution of the fetish-like 'objectivity of value' and is a different matter from the analysis of the quantitative proportion in which complex labour 'counts as' multiplied simple labour. In his 'asocial' misreading of Marx's critique of political economy, Böhm-Bawerk conflated these two clearly distinct issues.

Furthermore, the 'social process' that according to Marx 'accomplishes' such reduction 'behind the back of the producers' is not, *pace* Böhm-Bawerk, the 'exchange process'. That social process actually is the *indirect* mode through which the social character of human productive activity attains its immanent unity when each production process is organised in the form of *private and independent labours* (Marx 1976a, 163ff.). As argued in the first two chapters, under these circumstances, the social character of individual labours that comprise the global labour of society is not consciously established on the basis of their concrete or useful character before they are actually exerted. Instead, it is recognised only '*post-festum*', and on the basis of their intrinsic *material* identity as qualitatively homogeneous productive expenditures of sheer human corporeality (brain, nerves, muscles, etc.), which, once objectified in the product, becomes *socially* represented as the thing-like attribute of the product that allows it to enter the exchange relation and manifest indirectly the human subject's immanent determination as an individual organ of social labour: the form of general exchangeability or the value-form. As Marx himself acknowledges, the scientific description of this social process and its practically-determined elimination of all material qualitative differences in the concrete commodity-producing labours might sound like an absurdity and certainly did so to someone like Böhm-Bawerk. Still, as Marx continues, this 'absurd form' is exactly the way in which the relation between the different private labours and the collective labour of society appears to the producers themselves when the human life process takes this historically-specific social form. Thus, it is not Marx's 'dialectical skill' that through wordplay substitutes 'count as' for 'to be', but the fetishised social form of capitalist production which, in a particularly violent manner, accomplishes the said 'substitution' which reduces all qualitative differences in human labour to quantitative ones.

Lastly, this means that there is no circularity in Marx's argument. For the social constitution of the value-objectivity of the product labour takes place within the immediate process of production and is therefore *presupposed* by the establishment of the exchange relation which only manifests, in a 'roundabout' way, the social determinations of individual labour already posited in the labour process.

Let us now turn to the critical assessment of post-Marxian contributions. The first attempt at a solution was that of Bernstein (1899), which, similarly to Himmelweit's (1984) more recent contribution, essentially comes down to grounding the higher value of the product of complex labour in the greater value of skilled labour-power. However, as other Marxists noted very early on in the debate, this explanation cannot but relapse into a theory of value founded on 'costs of production' instead of explaining the value of commodities on the basis of the living labour objectified in its production. Moreover, insofar as it revolves around the process of formation of the general rate of profit in the circulation process, Himmelweit's approach in particular certainly falls prey to Böhm-Bawerk's accusation of circular reasoning.

In their response, Hilferding–Bauer and their followers obviously thought that their reduction procedure avoided Bernstein's error of grounding the value of the product of skilled labour in the value of skilled labour-power. However, as hinted at by the aforementioned critics of the 'classic' solution (Bidet 2007; D. Harvey 2006; Tortajada 1977), it seems to us that by including in the value of the product of skilled labour the socially necessary labours required for the production of skilled labour-power, they end up relapsing into a similar elementary mistake, namely: the conflation of the value of labour-power (the 'past labour' objectified in it) and its use-value (the value-positing capacity of living labour in act). In effect, regardless of the degree of complexity embodied in the worker's labour-power, there can be no trace of the past labour required for the production of skilled labour-power in the 'multiplied' value-positing powers of skilled living labour in act. In this sense, the labour of the 'technical educator' or the labour objectified in a textbook is hardly different from those labours objectified in the most prosaic of commodities that the worker consumes during their lunchtime. Assuming that they have the commodity-form, they are all part of the privately-undertaken socially necessary labour required for the production of the commodity labour-power and, in that condition, they are absolutely independent of the labour that the worker will perform when setting their labour-power into motion in the capitalist labour process (Marx 1976a, 300–1).

Let us now consider the main solutions that have proliferated after the demise of the 'classic' paradigm as reviewed above, starting with those that treat the greater complexity of labour as involving a higher *productivity*. The first critical point to make in this regard is that these solutions tend to conflate different determinations of labour which are clearly distinguished in the Marxian explanation of value. This conflation is particularly pronounced in the case of P. Harvey (1985), whose argument, as we have seen, adds the *intensity* of labour to the mix: his explanation of the multiplied value-creating powers of skilled labour is simply based on an analogy with more intensive labour. However, it seems to us that such an analogy does not stand scrutiny. It is self-evident that a 'sculptor' could engage in an identical (socially necessary) extensive and intensive expenditure of their bodily productive powers than a 'stone-breaker', but their labour would nonetheless still involve a greater complexity: the former's labour-power would still need a longer period of learning before it could be expended productively, which would thus need to be reflected in a higher magnitude of value of its product of labour. Things get onto even shakier ground with the explanation of the augmented value-creating powers of more skilled labour on the basis of their alleged greater physical productivity. In the first place, more productive labour involves, in its very definition, that 'it provides more product in the same time', and given that 'a definite quantity of labour time continues to be represented in the same magnitude of value', 'it lessens the value of the commodity' since 'it curtails the labour time during which the same commodity can be produced' (Marx 1988, 334). By contrast, as we shall see in more detail below, and as even Böhm-Bawerk was (reluctantly) ready to admit to Grabski, skilled labour involves *a greater* expenditure of labour for the production of a commodity. In the second place, the association between complexity and *physical* productivity of labour is also rather problematic. For while comparative analysis of the latter always refers to the production of the *same* use-value, at stake in the former is the comparison between labours that produce *different* use-values.

This latter confusion can be also found in Bidet's (2007) own association of greater complexity of labour and higher productivity, although for another reason. In the case of this author, the confusion comes up in the first step of his idiosyncratic solution to the reduction problem, which, as we have seen, consists in drastically 'delinking' the special productive qualities of complex labour-power and its multiplied value-positing capacity. In turn, this connection is severed by arguing that in the context of the subsumption of labour under capital, value-positing is the product of the collective labourer of the workshop as a whole. Therefore, Bidet concludes that it is meaningless to 'individualise the incidence of specialised labour on the increase in value' (29). Now, while it is true that at the systematic level of the *real* subsumption of labour to capital, the commodity proves to be the result of the combined productive activity of the collective worker, we think that Bidet's conclusion regarding the vanishing of the incidence of skilled labour is too hasty, and actually does not follow from the said premise. Certainly, in Chapter 13 of *Capital* on 'Co-operation' Marx remarks (1976a, 440–41) that with the determination of individual wage-workers as members of a directly collective productive body within the workshop, the value they produce comes to be the *organic* result of their collective working day, so that 'each individual man's day is an aliquot part' of the latter. Thus, 'whenever a certain minimum number of workers are employed together', individual qualitative differences from the average worker 'compensate each other and vanish' (440). The point is therefore that the consequence of the determination of the collective labourer as the material subject of value-positing is the practically-objective constitution of commodity-producing labour as *average social labour*. However, the kind of qualitative divergence in the individual productive attributes of wage-workers that Marx refers to in these pages is *not* the one that derives from '*acquired*' skills (which are those that count for the determination of complex labour). Rather, he clearly refers to the cancelling out of individual differences in '*natural*' skills, and therefore to one of the aspects of the reduction of *individual* to *socially necessary* labour. But there are no reasons why the formation of the collective labourer would make the incidence of 'specialised labour' on value-production vanish. Here it is important to remember that at stake in the complex labour reduction problem is the production of two *different use-values*. And even if each commodity is now considered as the immanent product of a collective labourer, what happens is simply the practically-objective constitution of an *average degree of complexity* or *skill level* for each 'workshop as a whole', out of their respective compositions of the individual ('acquired') skills of its members. The greater the average degree of complexity of a certain collective labourer, the (proportionally) greater the magnitude of value produced. In sum, qualitative differences derived from divergences in 'acquired' skills do not vanish with the formation of the collective labourer as the material subject of capitalist commodity production. The complex labour 'reduction problem' therefore still stands unsolved.[12]

The remaining group of contributions to examine is that which approaches the skilled labour reduction problem by resorting to capital's tendency for the universal and absolute deskilling of human labour in its search for relative surplus value (Carchedi 1991, 130–34; D. Harvey 2006, 57–61; Itoh 1987; Kay 1976; Sekine 1997, 39; 2020, 193–96, 205–6, 558; Uno 1977, 32n2). There are at least three issues which undermine this attempt at a solution. In the first place, as we have already seen (and will discuss further below), according to Marx the treatment of this reduction pertains to the level of abstraction of the *simplest determinations of value* (a fact that his critics like Böhm-Bawerk perceptively and duly noted). Without solid grounds for the value-form already established at that systematic level, the whole subsequent development of form-determinations cannot but rest on shaky foundations. But this is precisely what happens if, as these scholars propose, the explanation of the reduction is deferred to the systematic level of the capital-form. One could of course decide, for presentational reasons, to postpone the full exposition of a certain determination until a more concrete level of abstraction is reached. But such an explanation must surely be *possible* to be developed at the more abstract systematic level, which certainly cannot be done if based on capital's tendency for deskilling. In the second place, even at a theoretical level, the tendency for the degradation of the productive attributes of wage-labourers is not the only one presiding over the transformations of the capitalist labour process brought about by the increasing automation process of large-scale industry (although the former is admittedly the one that captured Marx's focus in *Capital*). As a matter of fact, large-scale industry also involves another tendency for the *expansion* of the productive attributes of the part of the collective labourer responsible for the advance in the conscious control of the movement of natural forces (that is, science) and its technological applications in the directly social organisation of immediate production process. Although not explicitly addressed by Marx in *Capital* (but see Marx 1976c, 1039–40), it is clear that the production of relative surplus value requires from these workers ever more *complex* forms of labour. As much as those discussed in *Capital*, these are also 'immediate effects of machine production on the worker' (see Starosta 2016, 233ff.). Finally, even if we disregard this other tendency, the fact remains that as all tendencies, that which deskills labour-power is only realised gradually or by degrees. Thus, special skills are not eroded overnight but through a long-drawn-out historical process. And as long as differences in the degree of complexity of different labours persist 'empirically', the question of the determination of the value of the products of skilled labour still stands in need of a solution.

The determination of complex labour in value-production

As argued above, a key insight in Marx's *analysis of the commodity* that needs to be recovered for the purpose of addressing the skilled labour problem is that it is the fetish-like value-objectivity that socially makes different commodities count as qualitatively identical and which, therefore, negates 'in practice' all qualitative differences intrinsic to the materiality of the varied kinds of labours that produce them. The *analysis of commodity-producing labour* must therefore consist in finding an underlying material qualitative identity behind its apparent varied concrete forms. Specifically, Marx identifies in chapter 1 of *Capital* three kinds of qualitative differences which appear at first sight to negate the role of labour as the homogeneous substance of value.

The first difference pertains to the determinate character of each concrete labour. Evidently, 'tailoring and weaving are qualitatively different forms of labour' (Marx 1976a, 134). As we have seen in the first chapter of this book, the qualitative difference immanent in the different forms of labour thereby becomes transcended in the determination of value-positing labour as a sheer expenditure of human labour-power, with those varied useful labours determined as 'merely two different forms' of that expenditure.

In the second place, there is the diversity in the individual expenditures of labour in the production of the same use-value. According to Marx (1976a, 129), these derive both from the differences in the dispositions and 'natural' abilities of commodity producers and, more fundamentally, from the technical conditions of production. In this respect, Marx argues that these differences are transcended by the value-form insofar as it is only the amount of individual labour-time that accords with the *normal* conditions of production and the average degree of skill and intensity that counts for the determination of the magnitude of value (129).

The third qualitative difference that comes up in the analysis of commodity-producing labour is precisely that which characterises complex labour, which we will therefore examine more closely. Marx (1976a, 134–35) notes here that ‘human labour-power must itself have attained a certain level of development before it can be expended in this or that form’. The analysis of labour as *actuality* now passes over to the analysis of labour-power as the human *potentiality* for that productive activity. Thus, the different labours which had been reduced to their common quality as mere productive expenditure of human corporeality, now turn out to be further differentiated qualitatively on the basis of the varying degrees of complexity of the respective labour-powers of which they are an expenditure. In the face of this distinction, Marx first reminds the reader the *lack of qualitative difference* with which ‘objectified labour’ appeared when it was discovered as the substance of the value. In effect, in the discovery of the content of the ‘ghostly objectivity’ of value, labour did not appear as the actualisation of a labour-power that has attained more or less development but as mere ‘homogeneous human labour’. Similarly to the previous two cases, the need to transcend this difference must consist in revealing the specific way in which the value-form extinguishes ‘in practice’ those different qualities in commodity-producing labour. In this case, Marx concludes that the labour represented in the value of commodities is ‘*simple average labour*’, i.e. ‘the expenditure […] of the labour-power possessed in his bodily organism by every ordinary man, on the average, without being developed in any special way’ (135).[13] Therefore, *through the value-form* all those labours whose performance requires a more complex labour-power are *socially* represented as a quantitative sum (or multiple) of units of simple labour, which results from the consequent *practical* reduction of the production of skilled labour-power itself to an accumulated expenditure of simple labour-power.

As we have seen, this explanation does not suffice to *qualitatively* specify the simple labours that must be considered in the production of more complex labour-power and, *therefore*, to be able to *quantitatively* establish the degree in which the value-positing powers of complex labour become multiplied. We have also seen that the subsequent Marxist debate also failed to approach the question in a manner which is consistent with the analysis of the commodity that Marx did provide in *Capital*. Let us, therefore, elaborate further on the value-positing powers of skilled labour on the basis of the simplest determinations of the value-form.

Following Marx’s analysis of the commodity, we have argued that only privately-undertaken social labour is value-producing. A first corollary of this is that only those simple labours which have been privately organised *vis-à-vis* the consumer of the product of complex labour must be considered as being socially represented in the latter’s value. The crucial question that follows is when does the private production of ‘complex commodities’ actually start? Under a mode of production in which social labour is privately-undertaken, the actual starting point of the organisation of any productive activity is the recognition by the private producer of a potentially solvent social need for a determinate use-value. Now, if the production of the latter actually requires the expenditure of a 'specially-developed' labour-power, the private organisation of social labour actually commences with an earlier step, namely, the production of a labour-power with the requisite determinate quality (hence complexity). Thus, the commodity-producer must firstly expend privately their simple labour-power with a view to developing the productive attributes that must be set into motion in order to produce the said 'complex commodity'. In other words, they must *learn* to make that potentially needed use-value. Note that this latter privately-undertaken expenditure of simple labour-power is exerted solely with the purpose of producing the 'complex' use-value under consideration. In this sense, it can hardly be distinguished from the expenditure of simple labour-power entailed by the production of the most 'prosaic' commodities. More concretely, it is part of the conscious expenditure of the bodily productive powers of the human being, which is organised in a private manner, and which, therefore, is an equally constitutive part of the socially necessary labour-time that becomes objectified as the value of its product. Thus, as Iñigo Carrera (2021, 83) puts it, complex labour 'is a simple expenditure of human labour-power whose initial purpose is not the production of a use-value which is external to the subject who is performing it, but the development of this very working subject's aptitude to produce' such more 'complex' use-values.

Now, the discussion so far might seem to just reinstate, maybe with greater precision, the classic 'Hilferding–Bauer' solution. But let us examine more closely the part of the production process that corresponds to the development of complex labour-power. At the start of the process, the commodity-producer is, as 'every ordinary human being', evidently endowed with *simple* labour-power. No prior expenditure of labour-power is needed to undertake the special development of their own labour-power. However, during the time in which they are learning their complex 'trade', the commodity-producer must obviously reconstitute the simple labour-power which has been expended in the learning process. And this means that they must consume certain use-values which, for the sake of simplicity, we shall assume that are all the product of privately-performed social labour, that is, commodities. What is more, the special development of their complex labour-power might entail the consumption of certain specific commodities beyond those necessary for the reconstitution of simple labour-power; for instance, the services of a 'technical educator', as usually exemplified in the classic Marxist discussion. It might then seem that all the social labour materialised in those commodities that reconstitute or further develop the labour-power of the complex commodity-producer during the learning process, must be included in the determination of the value of the product of skilled labour. Indeed, those labours appear to have no purpose other than the production of a skilled labour-power and, through this mediation, the production of the 'complex commodity' under consideration. As a matter of fact, this is the conclusion drawn by the classic solution. However, we think that this conclusion is faulty and is the source of the aforementioned confusion of constant and variable capital rightly highlighted by critics of the classic solution.

In effect, as follows from Marx's theory of the value-form, the labour objectified in the commodities consumed by the private owner of labour-power for the sake of their personal material reproduction does not enter the formation of the value of the commodity that they produce. The reasons for this are quite straightforward. At the level of abstraction of the simple circulation of commodities, the final goal of the social metabolic process is the 'consumption, the satisfaction of needs, in short use-value' (Marx 1976a, 135). It thereby follows that when those commodities needed for the production of labour-power are consumed by the commodity-producer, the transformation of the materiality of those means of subsistence into productive attributes of the human subject brings this particular cycle of social reproduction to a close. The labour objectified in them, which had been privately-undertaken, thus achieves final recognition as socially-useful and so do their products as social use-values which, through the consumptive appropriation of their materiality, are eventually realised. And as these commodities' social use-value is definitively extinguished through their use or consumption, so is the value of which they were 'material bearers'. Thus, when the commodity-producer in question undertakes the organisation of the private production of a use-value that they deem socially-useful (whether simple or complex), no trace of the value of the commodities they had consumed to produce their labour-power actually exists. In fact, a *new* cycle of social reproduction starts afresh, which might (or not) yield a social use-value, whose consumption by another member of society will bring the former to a close.

In brief, our point is that the only simple labours that become condensed in the 'direct' labour that produces use-values external to the working subject, and which thereby turn into complex labour, are those privately-performed by the commodity-producer in order to develop the productive attributes of their labour-power that were subsequently set into motion in the direct production process of the respective use-value. To put it in terms of the classic debate, the only labour that enters the determination of the multiplied value-positing powers of complex labour is that of the 'student'. Hilferding's and Bauer's respective mistake, uncritically reproduced by all those other Marxists that followed their flawed solution, was to lump the student's labour together with that of the 'technical educator', thus overlooking the fact that the latter and the former play entirely different parts in the social production process.

All this discussion allows us to draw two fundamental preliminary conclusions. In the first place, the differences in complexity of the varying commodity-producing labours are overcome 'in practice' by the value-form through the social representation of all objectified labour as an accumulation of simple labour. In the second place, the higher value of the product of skilled labour is actually explained by the same determinations as in the case of any other commodity: by the privately-performed socially necessary abstract labour required for its production. The key, however, resides in being absolutely clear and precise about which private labours are socially necessary *just* for the production of the *product of skilled labour*. And these come down to the living labour of the skilled worker, the 'dead' labour objectified in the means of production utilised by living labour in the production process and, crucially, the labour expended *by the skilled labourer themselves* (and *not that expended by the 'technical educator'*) with a view to acquiring the skills which are *socially necessary for the production of the said 'complex commodity'*.

Now, as should be methodologically evident, this latter conclusion cannot be altered when we consider value-production as a moment of the production of capital. Under the command of capital, commodity production is mediated by the determination of labour-power as a commodity (Marx 1976a, 271). Consequently, what we previously considered as a single private production process becomes split into two separate processes: one which produces the commodity 'complex labour-power' and another that produces a 'complex commodity'. Furthermore, when subsumed under capital, the goal of social production is no longer the satisfaction of needs but the valorisation of value. Hence, in capitalist society, the process of individual consumption does not bring each cycle of the process of metabolism to a close. The latter moment is reached in the sphere where labour-power is consumed for the production of more value than its reproduction costs, which is the phase of *productive* consumption or the labour process (Starosta and Caligaris 2016). The process of value-production of the product of complex labour must be reconsidered in light of these more concrete determinations.

As argued above, this process starts with the development of skilled labour-power by the labourer themselves. But now the material unity between this phase of the production process and the actual making of the 'complex commodity' is formally mediated by capital's purchase of (skilled) labour-power as a specific commodity 'whose use-value possesses the peculiar property of being a source of value' and which, 'like all other commodities […] has a value' (Marx 1976a, 270, 274). The latter is the value of the commodities that the wage-worker has consumed for their own material reproduction which, insofar as the cycle of social reproduction no longer ends with individual consumption but with the valorisation of capital, reappears as the value of the commodity labour-power, instead of being annihilated through the consumption of means of subsistence, as happened with the simple commodity-producer.[14] Thus, capital purchases complex labour-power alongside the requisite means of production to set the valorisation process into motion. In this process, the concrete living labour of the wage-worker transfers (hence preserves) the value of means of production onto the product. But things are different with the value of labour-power. As (skilled) labour-power is effectively consumed (and thereby exploited) by capital in the immediate production process as a specific commodity which can produce surplus value, its use-value suffers final appropriation and, with that, its value is definitively extinguished. On the other hand, that very consumption of labour-power by capital privately produces new 'complex commodities' and hence, new value (which reproduces variable capital and yields surplus value). Crucially, note that in this process *absolutely no trace of the privately-performed past social labour required for the production of skilled labour-power remains in need of recognition of its social usefulness. Hence, not an 'atom' of that part of social labour must be represented as the value of the product of skilled labour*. As happened at the level of abstraction of simple commodity production, the value of the product of skilled labour is solely formed by the simple individual labour expended by the wage-worker in the production of their skills, the new living labour they perform to make the 'complex commodity' and the value of means of production (that they preserve at no cost for capital).

Now, at first sight, this discussion seems to clash with Marx's repeated remarks that skilled wage-labourers produce more value per unit of time than simple labourers in a ratio that reflects the higher value of their labour-power, so that the rate of surplus value remains identical in both cases (see Section 'Marx on skilled labour' above for references). However, we think that it is possible to make both arguments consistent. In our view, Marx was probably assuming that the use-values needed for the daily reproduction of each type of labour-power are quantitatively and qualitatively identical (and that their respective 'retirement ages' are equal). Thus, for each day that the skilled labourer spends on the acquisition of their skills, there will be an equally proportional increase in both the value of their labour-power and their multiplied value-positing powers. Although this identity of 'consumption norms' could sound problematic from a contemporary viewpoint, it might have been reasonable for Marx to make that assumption in a historical period when he observed a high degree of, and growing tendency for, homogeneity in the conditions of material reproduction of wage-workers. Thus, rather than postulating a *causal link* between the higher value of skilled labour-power and its multiplied value-positing powers, we think that Marx was simply taking the former as a relatively accurate *'observable' indicator* of the latter.[15] Nevertheless, this does mean that any qualitative or quantitative difference in the respective daily consumption requirements of skilled and simple wage-labourers, necessarily implies the existence of different rates of surplus value. But, as argued elsewhere, this implication does not compromise the validity of Marx's explanation of the source of surplus value in the exploitation of the wage-worker (Starosta and Caligaris 2016).

Conclusion

This chapter has critically examined the controversies over the determination of complex labour in value-production and offered an alternative solution which is consistent with the Marxian critique of political economy. Key to this endeavour has been the recognition that Marx's own treatment of the question is at the very least incomplete. Thus, although we showed that the critiques of the Marxian solution do not rest on solid foundations, Marx certainly did not spell out (or at least not systematically enough in light of subsequent controversies) the *qualitative* determination that specifies the simple labours that constitute complex labour, and whose *quantitative expression* is manifested in the degree in which its value-positing powers become multiplied.

In our reconstruction of the history of the 'skilled labour' debate, we have critically reviewed the different solutions put forward by Marxists and showed that none of them manages to remain consistent with the foundations of the Marxian critique of political economy. By contrast, we have offered an alternative approach that is grounded in a rigorous reading of the 'analysis of the commodity' presented in the opening pages of *Capital*. In the first place, we argued that the differences in the complexity of labour are eliminated in practice through the value-objectivity characterising the commodity-form of the product of labour. In effect, the labour objectified in the commodity becomes *socially* determined as simple labour as far as its historically-specific role as substance of value is concerned. In the second place, we argued that the degree in which complex labour counts as a multiple of simple labour in value-production is solely determined by the expenditure of simple labour-power that the complex labourer needs to undertake in order to produce their own specially-developed labour-power.

Notes

1 Similar critical arguments that emerged around the same time can be found in the works of Block (1884, 133), Adler (1887, 81–85), Pareto (1998, 299ff.) and Flint (1906, 147–49).

2 Bernstein draws upon a work by Buch (1896), who attempted to place value theory on 'physiological' foundations by focusing on the *intensity* of labour and taking variations of wages as indices of the different degrees of intensity. Buch's contribution also influenced Liebknecht's (1902, 102–3) proposed solution to the 'reduction problem', which consisted in the representation of complex labour as more intense, thus involving a greater expenditure of energy.

3 Despite Hilferding's trenchant critique of Bernstein, the connection between the value of complex labour-power and the value of its product has not been left completely behind in the literature. See, for instance, Cutler et al. (1977) and Hiroyoshi (2005).

4 Although Bauer drew on Deutsch on the 'reduction problem', he parted company with the latter's argument concerning the determination of the value of complex labour-power. Thus, Deutsch (1904, 23ff.) included the student's labour of 'self-education' in the cost of production of skilled labour-power and therefore concluded that the rate of surplus value of the skilled labourer is necessarily lower than that of the simple labourer. By contrast, Bauer considered that the student's labour of 'self-education' does not enter the determination of the value of their labour-power. As a consequence, the rate of surplus value of the skilled labourer is actually *higher* than that of simple labour.

5 This reading continues to be highly influential to this day. See, for instance, Cockshott and Cottrell (1993, 23ff.); A. Lapidus (1993); Cotrim (2015); Greenblatt (2017).

6 An exception to this broad consensus from the Neo-Ricardian camp is the contribution by Bowles and Gintis (1977), who sidestepped the reduction problem through a mathematical model which determined the rate of profit and the prices of commodities by expressing the different skill requirements in the diversity of wages for each type of labourer. However, as Itoh (1987, 46) argued, this approach solved the reduction problem by simply making redundant the very concept of labour. Be that as it may, Bowles and Gintis's intervention generated a lively debate among Neo-Ricardians (Bowles and Gintis 1978; 1981; Catephores 1981; Krause 1981; McKenna 1981; Morishima 1978; Steedman 1985).

7 This critique had actually been pioneered by Schlesinger (1950, 129); see also Ciafardini (1975). An antecedent to Tortajada's critique of the classical solution can be found in the pages of the 1974 issue of *Annales de la Faculté de Droit et des Sciences Economiques de Reims*, where the different contributions referred to the Hilferiding–Bauer approach as the 'theory of value transfer' (Duharcourt 1974; Dumasy 1974; Rasselet 1974; Victor 1974).

8 This solution clearly resonates with the so-called 'deskilling thesis' formulated in the seminal work by Braverman (1998). As we comment below, this thesis is a one-sided reduction of the two-fold movement of degradation *and* expansion of the productive subjectivity of the collective labourer required by the system of machinery to one of

its moments. See Iñigo Carrera (2013, 42). One of the immediate reasons behind such a unilateral account lies, as Tony Smith (2000, 39) points out, in its very restricted definition of 'skill', very much referring to manufacturing skills.

9 The consideration of more complex labour as more productive is actually quite old and was pioneered by Boudin (1920, 113–17). See also Rasselet (1974) and Duharcourt (1974).

10 This train of thought had already been developed by Kidron (1968). More recently, it has been advanced by Choonara (2018).

11 We examine Bidet's 'circulationist' explanation of extra surplus value in the next section.

12 The second step in Bidet's argument is to submit that a collective labourer with a higher composition of skilled labourers does experience an increase in the 'overall productivity of the workshop'. And since in his particular take on the source of extra surplus value, which Marx discusses in chapter 10 of *Capital*, exceptionally productive labour is seen as creating in equal periods of time greater values than average social labour of the same kind (Bidet 2007, 20–21), a greater incidence of 'specialised labour' in a collective worker leads to a concomitant increase in the amount of value produced. In our view, that an increase in the productivity of labour allows the respective individual capital to temporarily appropriate an extra surplus value, does not change the fact that 'a definite quantity of labour time continues to be represented in the same magnitude of value' (Marx 1988, p. 334; see Chapter 6 of this book). In effect, if value-positing is a process taking place in production and not in circulation, and provided that the total extensive and intensive expenditure of labour-power does not change as a result of the introduction of technical innovation, it follows that the total mass of value produced remains the same before and after the productivity increase. Besides, we have seen that explanations based on the association of complexity and productivity conflate determinations pertaining to the production of different use-values with those pertaining to use-values of the same kind.

13 All labour-power needs at least *some* prior expenditure of human labour with a view to developing the productive 'mental and physical capabilities existing in the physical form, the living personality of a human being' (Marx 1976a, 270). *Simple* labour power is that whose requirements of prior 'learning' are the minimum which is necessary to perform productive labour in a given society. It, therefore, changes as the development of the productive powers of social labour transforms the *normal* material constitution of human productive subjectivity. This is the reason why Marx clarifies that simple labour 'varies in character in different countries and at different cultural epochs, but in a particular society it is given' (135). See Iñigo Carrera (2021, 52–53).

14 See Starosta and Caligaris (2016) for a more extended discussion of this.

15 Against this backdrop, it is noteworthy that in the French edition of *Capital*, Marx decided to remove the sentence which stated that the expenditure of complex labour was represented 'in proportionally higher values' (Marx 1872, 84; 1976a, 305).

5 Rethinking the determination of the value of labour-power

Introduction

Although probably not as widespread as debates on the simpler determinations of the value-form, the commodity-form taken by labour-power and, *a fortiori*, the determination of its value, have also been at the centre of the controversies surrounding the Marxian critique of political economy. However, the discussion has not shed much new light on the central question about the determination of the use-value composition of so-called ‘wage-goods’ consumed by workers. Yet, as some authors have pointed out (e.g. Fine et al. 2004), the nature of those means of subsistence is a fundamental element of Marx’s account of the value of labour-power. Despite this centrality, the use-value dimension of the worker’s consumption has not been a fundamental matter of inquiry. A possible reason for this can be found in what seems to be a widespread implicit consensus on the determination of the range and quality of use-values that enter into the determination of the value of labour-power. For most Marxists, the consumption bundle of the working class involves a two-fold determination. On the one hand, it is determined by the need to guarantee the ‘physical’ reproduction of workers. On the other, it is determined by the class struggle. It is this latter component which, allegedly, sets Marx’s approach apart from Ricardo’s ‘beast of burden’ view of the determination of the ‘value of labour’ (Rubin 1989, 279), thereby going beyond the ‘iron law of wages’ that reduced their level to that which is strictly necessary for the biological reproduction of workers.

The first aim of this chapter is to challenge this received wisdom on the determination of the value of labour-power. In particular, we take issue with the aforementioned ‘two-component’ account of the determination of working-class consumption, i.e. with the view that posits the material reproduction of workers and the class struggle as two *independent* factors that determine the number and type of ‘wage-goods’. On the one hand, despite its widespread acceptance among Marxists, this reading has no solid textual basis on Marx’s major economic works. On the other hand, and more importantly, we will argue that it rests on a problematic separation of the actual immanent unity between materiality and social form in the capitalist mode of production. In effect, once the qualitative and quantitative composition of the use-values that enter into the determination of

DOI: 10.4324/9781003201939-6

the value of labour-power is seen as *determined* (wholly or in part) by the power relations between social classes, working-class consumption is inevitably rendered external to the historically-specific social form taken by the materiality of the metabolic process of humanity, i.e. capital. More concretely, we will show that the two-component perspective on the consumption bundle of wage-workers overlooks the material basis that *grounds* the potentiality of working-class struggles over the conditions of reproduction of labour-power. As we will see, this foundation lies in the transformations of the productive attributes of the collective labourer that result from capital's search for relative surplus value through the material revolutions in the labour process.

In this sense, the second aim of this chapter is to propose an alternative approach to the determination of the value of labour-power that re-establishes the inner connection between the materiality of the process of production and its social form. Specifically, we argue that the value of labour-power is determined by the value of the commodities that wage-workers need to consume in order to reproduce the materiality of the *whole range of productive attributes* that capital demands from them at different times and places; including both the 'technical' manual and/or intellectual skills and knowledge, and what we shall term 'moral' attributes. On these grounds, the chapter further argues that the class struggle does not *determine* the value of labour-power; it only *mediates* its full *realisation*.

The 'received wisdom' and its limits

As mentioned above, most if not all Marxists tend to take for granted that the class struggle determines, at least in part, the customary living standard implied in the reproduction of the class of wage-workers. There are, however, variations within this theme.

At one end of the spectrum, some scholars conceive of the class struggle as the fundamental (or rather, the only) determinant of the value of labour-power. For instance, this is the case of authors belonging to the so-called 'New Solution' perspective, who have questioned the commodity nature of labour-power on the grounds that it is not the product of a capitalist production process (Mohun 1994). As Mavroudeas (2001, 55) perceptively notes, the implication of the 'New Solution' approach is that the value of labour-power must be considered, in a rather Smithian fashion, as the quantity of *labour commanded* by the money-wage, which in turn is solely determined by the class struggle in the sphere of distribution (or maybe mediated through specific institutional arrangements). The 'Autonomist' theory of the political determination of the wage can also be seen as sharing in this broad perspective, albeit with a more orthodox focus on the class struggle in production (thus preserving the link between socially necessary labour-time actually expended in the production of 'wage-goods' and the value of labour-power, which is lost in the 'New Solution' approach) (Cleaver 2020, 80–85; Negri 1991, 132–33). Despite their differences, however, for both perspectives, the determination of the value of labour-power ultimately comes down to a simple expression of power relations between social classes. There are two problems with this. Firstly, the objective social basis of the respective power of each social class is left without explanation. More importantly, since thus conceived the value of labour-power bears no relation to the conditions in which labour-power is expended in the direct process of production, all connection is lost between the reproduction of the capital relation and the materiality of the human metabolic process in its unity (i.e. the nexus between social production and consumption).

However, the majority of Marxist scholars tend to support a more nuanced view that hinges on the distinction made by Marx (1976a, 275) in chapter 6 of *Capital* between the 'physical' element of the value of labour-power ('natural needs, such as food, clothing, fuel and housing') and the 'historical and moral' component (i.e. needs 'which depend therefore to a great extent on the level of civilization attained by a country' and 'on the conditions in which, and consequently on the habits and expectations with which, the class of free workers has been formed'). Insofar as the former element is usually seen as somehow linked to the recovery from the prior expenditure of labour-power in the direct production process, the materiality of the reproduction of the wage-labourer is taken into consideration by this approach. However, these authors add to what they consider to be the strictly material element of the value of labour-power, a historical and social element constituted by the customary standard of living, which in turn is seen as determined by the class struggle.[1] Whilst this perspective on the value of labour-power is more rigorous and consistent with the Marxian critique of political economy, it is not itself exempt from shortcomings.

The first thing to note is that despite its widespread acceptance among Marxists, the idea of the determination of the value of labour-power by the class struggle has no supporting textual evidence from Marx's writings. There is no single passage in *Capital* (or in other works for that matter) in which he states that the average amount and qualitative nature of means of subsistence results from the balance of class forces. More specifically, at no point does Marx state that, in contrast to the physical element of the value of labour-power, the historical and moral element is constituted by the class struggle. What he does say is that the latter component expresses the specific conditions inherited from pre-capitalist social relations underlying the history of the genesis of each national fragment of the global working class, i.e. the 'general level of civilization' attained in a particular place at a particular time. In Marx's (1985, 145) own words, 'the important part' in the determination of those social conditions is not played by the class struggle but, as he puts it in *Value, Price and Profit*, by 'historical tradition and social habitude'.

Incidentally, it is from that Marxian text from which some scholars draw the textual evidence for the idea of the class struggle as determining the value of labour-power; for instance, this is the case with Kenneth Lapides's (1998) detailed study on *Marx's Wage-Theory in Historical Perspective*. However, in those passages, Marx only states that the fixing of the actual degree of *profit* among the immense scale of possible variations up to its maximum is settled by the continuous struggle between capital and labour. This maximum corresponds to the 'physical minimum of wages and the physical maximum of the working day' (Marx 1985, 146). In other words, it corresponds only to the physical component of the value of labour-power. Thus, what Marx discusses in that work is the extent to which the class struggle manages to make the actual level of the *wage* approximate the full value of labour-power, which includes the traditional living standard above the physical minimum. In fact, in *Capital*, the situation of a price of labour-power falling below the traditional living standard to its minimum is characterised by Marx (1976a, 277) as involving the purchase of labour-power below its value. But he does not state that the traditional standard of living itself (and *a fortiori* the full value of labour-power) varies according to the ebbs and flows of the class struggle.

This takes us to the second issue to be considered here, which is fundamentally methodological. Even if we set momentarily aside the question about the connection between the class struggle and the determination of the value of labour-power, there is a problematic aspect to the received wisdom on the two components reviewed above. For in that reading, the 'historical and moral' component is seen as a generic feature of the value of labour-power whose content and definition are exhausted in chapter 6 of *Capital*. However, that perspective overlooks the systematic place and significance (i.e. the level of abstraction) of Marx's reference to that aspect of the value of labour-power. More specifically, that reading misses the point that Marx introduces his comment on the 'historical and moral' component in the context of the *formal subsumption of labour to capital*. That means that at that stage of the exposition, the determination of the value of labour-power is an external, given presupposition to the movement of capital. The reason for this is that the labour process itself, and therefore also the materiality of the physical and intellectual productive attributes of wage-workers and the consumption basket needed to reproduce them, are at that stage external to the reproduction of the capital-form. In this sense, one could argue that the discussion in chapter 6 of *Capital* corresponds to the *simplest* or *most abstract* determination of the value of labour-power. However, we shall argue that the determination of the value of labour-power is not exhausted at that abstract level but involves further concretisation as we move from the formal to the *real subsumption of labour to capital*, and from the latter to the reproduction of the total social capital. Now, before elaborating further on these issues, it is firstly necessary to probe deeper into the simplest determination of the value of labour-power. We do this in the next section through a critical examination of Marx's own views as presented in *Capital*.

Marx's discussion of the most general determinations of the value of labour-power in *Capital*: a critical reading

Let us start by noting a methodological tension running through Marx's exposition itself. As in many other places in *Capital*, in this discussion, Marx tended to present the *systematic* content of his argument (hence the general determination at stake) through the concrete *historical* form of realisation of that determination. Thus, whereas from the systematic point of view, the only relevant point to make was the *externality* of the value of labour-power as a '*conceptual*' presupposition *vis-à-vis* capital's movement of self-valorisation, Marx presented this determination as constituting a *historical* presupposition of the capitalist mode of production. In effect, we have shown that he considered that customary standard of living as a result of capital's 'pre-history', which is carried over by what he faced as the geographically variegated 'habits and expectations' of the class of free wage-workers. This presentational strategy is not without merits. For what can be more external to capital than that which has been inherited from *pre-capitalist* social forms? The downside is that it risks muddling the systematic and historical strands of the argument.

Be that as it may, the main thrust of Marx's (1988, 42) argument about the determination of the quantity and quality of the bundle of commodities that constitutes the value of labour-power is that it is resolved into what is 'needed to maintain it, i.e. to maintain the worker's life as worker, so that having worked today he will be able to repeat the same process under the same conditions the next day'. As Marx (1976a, 275) puts it in chapter 6 of Volume I of *Capital*, 'the means of subsistence must therefore be sufficient to maintain him in his *normal state* as a *working individual*' (emphasis added). Several key issues follow from this.

In the first place, this implies that it is the consumption of those means of subsistence that (re)produces 'the muscles, nerves, bones and brains of existing workers' (Marx 1976a, 717) that materially bear 'the aggregate of those mental and physical capabilities which he sets into motion whenever he produces a use-value of any kind' (270). In other words, it is through the appropriation of those use-values that the worker (re)produces the *materiality* of their *productive subjectivity* which, as Marx discovered as early as 1844, is nothing more (but also nothing less) than their human individuality or species-being. Consumptive activity, therefore, reproduces the materiality of the specifically-human attributes of the individual: their productive consciousness and will, i.e. 'what distinguishes the worst architect from the best of bees' (284). The other side of the same coin, however, is that the 'amount and quality of the means of subsistence, and therefore also the extent of needs' (Marx 1988, 42), that enter into the wage-worker's consumption bundle, can have no material determination other than that which is necessary to reproduce whichever specific form the productive 'ability, aptitude and power enclosed in the living body of the worker' takes 'at a certain level of civilization'.

Furthermore, this raises the question as to what exactly Marx means by the '*normal* state as a working individual'. A first self-evident but trivial answer is that the wage-labourer must be able to act in the particular labour process in which they usually take part. However, a passage quoted above from the *1861–1863 Manuscripts* is a little more specific: they must be able to repeat their participation in the labour process *in the same conditions* as the previous day. The question, therefore, turns to what is entailed by those conditions. In many passages, Marx gives the impression that he has in mind only the *physical* reconstitution of the wage-worker as implicated in the normal state of their labour-power. Thus, in chapter 6 of *Capital*, he explicitly refers to those same conditions in relation to health and strength (Marx 1976a, 275). At some point in the *1861–1863 Manuscripts*, he adds 'vitality in general' to the list (Marx 1988, 51). These formulations can lend themselves to the association of the normal state of labour-power solely with the so-called ‘physical’ component of the value of labour-power. However, two arguments militate against this reading.

Firstly, in those preparatory manuscripts, just a few lines below, Marx (1988, 51) introduces a clarifying remark stating that ‘it is hardly necessary to mention here that the head belongs to the body as well as the hand’. We take it to mean that the normal state as a working individual involves not only fully functioning physical capabilities but also *mental* capabilities whose aggregate constitutes labour-power in its unity according to Marx’s own definition. This is to some extent self-evident insofar as the particular concrete labour performed by some wage-workers might involve mainly intellectual activity (e.g. academic labour). Both Marx’s stress on the physical ‘wear and tear’ of labour-power and his clarification that mental capabilities must not be forgotten, might have to do with the fact that in his time the great majority of workers performed mainly manual labour in the direct production process and intellectual wage-labour was scarcely developed. However, we shall argue below that much more is involved in the normal reproduction of those mental capabilities than what Marx insinuates. Secondly, Marx in *Capital* is unambiguous and states that the reduction of the price of labour-power to a magnitude which only covers the ultimate minimum given by the *physically* indispensable means of subsistence, involves its fall below its value. As we see it, the upshot of this is that for Marx it is the overall customary living standard, *including* the ‘historical and moral’ component, which constitutes the wage-labourer’s ‘normal state as a working individual’.

Now, once we rule out the idea that the *normal* conditions of purchase of labour-power that determine its full value do not come down to the physical or narrowly technical aspect of the wage-worker’s productive attributes, and consider that the customary dimension of working-class consumption can no longer be referred back to a pre-capitalist residue or is not determined by the class struggle, the question about the determination of the ‘historical and moral’ component still remains unanswered. Unfortunately, Marx’s own writings do not *explicitly* pursue the issue any further. However, we think that implicit in other texts that have not captured the attention of most commentators, it is possible to find the elements for a reconsideration of the determinations of the value of labour-power which can address the unanswered question about the ‘historical and moral component’.

Rethinking Marx’s account of the determinations of the value of labour-power

This latter point dovetails with another key issue worthy of discussion following from Marx’s simplest definition of the value of labour-power. It also relates to the aforementioned broader significance of the mental capabilities that comprise labour-power. For the productive attributes of workers (and so their productive subjectivity), do not just include those that are strictly necessary for the labour process in a restricted technical sense (the specific knowledge required for the performance of the determinate productive tasks under their individual responsibility). Additionally, they comprise what, in keeping with Marx’s terminology of the historical and moral component of the value of labour-power, can be referred to as 'moral' attributes as well. By this we mean the aggregate of determinate forms of consciousness, self-understanding, attitudes and dispositions that *also* need to be set 'into motion whenever [the workers] produc[e] a use-value of any kind' (Marx 1976a, 270). These moral attributes are of course not natural but the product of history, and therefore vary with the 'level of civilization' attained by society, i.e. with the historically-specific technical configuration of the production process that constitutes the general material basis in each phase of capitalist development. Moreover, they differ for each partial organ of the collective labourer in accordance with the differences in the productive functions that each of them respectively undertakes under the command of capital. Crucially, primordial and generic among those moral attributes (hence cutting across every segment of the working class) is what, as argued elsewhere, constitutes the most general form of subjectivity taken by the alienated consciousness of the human individual in the capitalist mode of production, namely: the personal freedom of the commodity producer (Iñigo Carrera 2021; Starosta 2016, chapter 6). This freedom from direct relations of authority and subjection which, as Marx (1973, 159) puts it in the *Grundrisse*, is but a concrete form of the human individual's 'subordination to their own social power in an objective form', is not simply an abstractly ideological, juridical or cultural form. It is first and foremost a *material* determination of the productive subjectivity of the human individual, a *productive power or attribute*. In reality, all those other dimensions of the moral productive attributes of wage-workers are diverse *specifications* of their abstractly-free consciousness as the *generic* determination of their subjectivity as private working individuals.

Maybe we can bring out this point more clearly by considering Marx's comparison of the wage-labourer and the slave in chapter 7 of *Capital* on the labour process. There, Marx initially shows that the doubly-free subjectivity of the wage-labourer suffers a first material/productive mutilation in the organisation of their direct production process *vis-à-vis* the simple commodity producer with which the dialectical exposition began. In effect, the first manifestation of the specific determination of the labour process as capitalist (i.e. as a process of consumption of the use-value of the commodity labour-power) is that 'the worker works under the control of the capitalist to whom his labour belongs' (Marx 1976a, 291). In other words, the capitalist now personifies the *productive consciousness* of the *unity* of the wage-worker's direct labour process in the name of their capital. In this sense, compared to the simple commodity producer, the wage-worker experiences a relative loss of the full control over the individual character of labour that constituted the specific material determination of the former's freedom. However, Marx notes in a footnote that unlike the case of the slave's reduction to an *instrumentum vocale* in antiquity, this material mutilation of the modern wage-labourer's productive subjectivity in the labour process is not total (303n18). Although through their direct control 'the capitalist takes good care that the work is done in a proper manner and the means of production are applied directly to the purpose' (291), i.e. that only socially necessary labour is expended, it ultimately remains the free wage-worker's individual responsibility that this is so (since the wage-workers' *objective* or *material* subjection to the 'dull compulsion of economic relations' constantly reminds them that acting responsibly is part and parcel of being a free person). This permits the introduction of more complex and sophisticated means of production *vis-à-vis* the modes of production based on slavery, in which only the 'rudest and heaviest implements are employed', since the slave reminds 'both beast and implement that he is none of them, but rather a human being [...] by treating the one with brutality and damaging the other *con amore*' (304). In other words, the sense of individual responsibility characterising the modern free subject is itself a productive force insofar as it expands the range and quality of means of production that can be set into motion in the direct labour process.

This *productive or material* determination of the wage-worker's formal freedom *vis-à-vis* the relative mutilation implied by the different relations of personal domination and subjection is developed by Marx with great depth and detail in the *Results of the Immediate Process of Production*. In those pages, he observes from the outset that although '*technologically speaking*, the *labour process* goes on as before, with the proviso that it is now *subordinated* to capital' (Marx 1976b, 1026), there already is a material development in the productive forces entailed by this *simplest* determination of the *formal* subsumption of labour under capital. Thus, with this 'formal change' in the social form of 'compulsion to perform surplus labour', there is an increase in the 'continuity and intensity of labour' and the establishment of social conditions which are 'more favorable to the development of *versatility among the workers*, and hence to increasing diversity in the modes of working and ways of earning a living' (1026–27). The following passage from this same text eloquently and concisely captures the determination of the 'idea' of personal freedom as a productive attribute *vis-à-vis* the slave:

> Compared to the independent artisan who makes goods for other customers, we observe a great increase in the continuity of labour of the man who works for a capitalist whose production is not limited by the haphazard requirements of isolated customers but only by the limits of the capital that employs him. In contrast to the slave, this labour becomes more productive because more intensive, since the slave works only under the spur of external fear but not for *his existence* which is *guaranteed* even though it does not belong to him. The free worker, however, is impelled by his wants. The consciousness (or better: the *idea*) of free self-determination, of liberty, makes a much better worker of the one than of the other, as does the related feeling (sense) of *responsibility*; since he, like any seller of wares, is responsible for the goods he delivers and for the quality which he must provide, he must strive to ensure that he is not driven from the field by other sellers of the same type as himself. The *continuity in the relations* of slave and slave-owner is based on the fact that the slave is kept in his situation by *direct compulsion.* The free worker, however, must maintain his own position, since his existence and that of his family depends on his ability continuously to renew the sale of his labour-power to the capitalist.
>
> (Marx 1976b, 1031)

In this sense, note that wage-worker's freedom from 'all the objects needed for the realisation of his labour-power' (Marx 1976a, 273) does not simply involve a relative mutilation *vis-à-vis* the simple commodity producer. It also entails a relative expansion of their productive subjectivity. Marx mentions in this quote the greater productive power derived from the greater continuity of work. But one should add the increased universality associated with the versatility also mentioned by him. By contrast, the *systematic* figure of the simple commodity producer (in the *historical* figure of the independent artisan) tends to be attached to a particular form of the means of production and hence to a restricted manifestation of their productive subjectivity (see Marx 1976b, 1033–34).

This development is furthered by both the content and the concrete price-form as wage of the determination of the value of labour-power, which gives 'scope for variation (within narrow limits) to allow for the worker's *individuality*' (Marx 1976b, 1032) in the determination of the singularity of their conditions of reproduction. Thus, the *average* value of labour-power for the working class as a whole is composed of *diverse* values of labour-power for organs of the collective labourer of different complexity; the wage cyclically oscillates around the value of labour-power; finally, even within the same 'trade', individual 'wages vary depending on the diligence, skill or strength of the worker, and to some extent on his actual personal achievement' (1032). 'Thus', Marx concludes, 'the size of his wage packet appears to vary in keeping with the results of his own work and its individual quality' (1032). This contrasts with the conditions of the material reproduction of the slave, for whom 'a *minimal wage* appears to be a constant quantity […] as something predestined, independent of his labour and determined by the mere needs of his physical existence' (1031–32). Individual productive qualities such as physical strength or special talent 'may enhance his value to a *purchaser*, but his is of no concern to him' since it does not impinge on their conditions of reproduction (1032). In sum, Marx concludes,

> The effect of all these differences is to make the free worker's work more intensive, more continuous, more flexible and skilled than that of the slave, quite apart from the fact that they fit him for quite a different historical role.
> (Marx 1976b, 1032–33)

What are the implications of all this for the simplest determination of the value of labour-power discussed above? Insofar as this freedom from relations of personal domination is a productive attribute as much as any other technical ability in a more restricted sense, it must be materially (re)produced in the same way as any other physical or mental capability of labour-power, namely, through the consumption of determinate use-values. Thus, the 'amount and quality of the means of subsistence, and therefore also the extent of needs' (Marx 1988, 42) of wage-workers must be consequently determined to include commodities that, both in their material attributes and in the manner of their practical appropriation, reproduce the form of personal freedom in which their subsumption to capital exists. In the section of the *Results* under discussion, Marx hints at this by remarking that insofar as the wage-worker ‘acts as a free agent’ when buying commodities ‘as he wishes’, ‘he is responsible for himself for the way he spends his wages. *He learns to control himself, in contrast to the slave*, who needs a master’ (Marx 1976b, 1033). He also notes in that context that ‘newspapers, for example, form part of the essential purchases of the urban English worker’ (1033), an ideological use-value that, generally speaking, is obviously not necessary for the reproduction of the specific technical skills of workers but crucial for the material reproduction of their free consciousness. In brief, the process of individual consumption of the worker does not only entail their self-production as a bearer of certain technical skills and knowledge but also as a personally-free productive subject. The necessary means of subsistence of wage-workers must, therefore, comprise all the use-values which are required for the reproduction of their material productive attributes in their unity: both the technical and the moral ones, with the ‘idea of free self-determination’ as the general foundation of the diverse manifestations of latter. Note, however, that the distinction between ‘technical’ and ‘moral’ attributes is fundamentally analytical; one cannot simply associate each kind of use-value with one or the other type of productive attribute.

With all these elements in mind, we would like to suggest a possible interpretation (or resignification) of what Marx might have been getting at with the distinction between the ‘physical’ and the ‘historical and moral’ component of the value of labour-power. Succinctly put, the former broadly corresponds to the (re)production of the strictly technical dimension of labour-power as defined above. Here we are quite simply sticking to the letter of Marx’s text (with the proviso that, as he further clarifies, the costs of education and training deriving from the degree of complexity of labour-power must be added to this physical component). Consequently, the point is rather uncontroversial and there are few disagreements among commentators. The key contentious issue hinges on the ‘historical and moral’ element which, as we have seen, without any solid textual evidence most Marxists take for granted as condensing the result of the class struggle. By contrast, our argument is that this other component of the living standard of workers condenses the *materially-determined* aggregate of use-values which are qualitatively and quantitatively necessary to (re)produce their productive attributes as a personally-free working subject who, through this freedom, affirms their objective subjection to the autonomised movement of the product of their social labour (capital).

Although it obviously does not constitute in itself a definitive piece of textual evidence, it is suggestive, in light of the previous discussion, that Marx (1976a, 275) submits that the ‘historical and moral’ element reflects ‘the conditions in which, and consequently on the habits and expectations with which, the class of *free* workers has been formed’ (emphasis added). In other words, it reflects the genesis of the wage-labourer not simply *qua* working individual but in their *historically-specific* determination as a *free* worker. As an alienated social form of organisation of the human life process, the valorisation of capital is specifically-predicated on the exploitation of the productive powers of *personally-free* labour. This is not merely an ideological-juridical veil that obscures in circulation the exploitative reality of the direct process of production (although the content of exploitation of the capital relation does objectively appear in that self-negated form). It is a historical determination of human productive subjectivity, i.e. of the conscious organisation of the appropriation of nature through the production of use-values in the labour process. Thus, *both* the technical attributes of labour-power and its general moral attribute as a personally-free subject are *productive requirements* of the reproduction of capital. In this sense, *both* are *fully determined* by the *material* conditions of the valorisation of capital in the production process.

The real subsumption of working-class consumption to capital

So far, we have discussed the simplest content of the determinations of the value of labour-power, pertaining as they do to the *formal* subsumption of labour to capital. Although these elements sufficed to make the point about the decisive role played by the material conditions of the productive consumption of labour-power in the determination of the aggregate of use-values that constitute the bundle of necessities of wage-workers, those material forms of the labour process were an external presupposition for the valorisation of capital. As a consequence, both the range of means of subsistence and the productivity of labour, were at that level of abstraction a given condition which capital only formally subsumes under its circulatory movement. The *value* of labour-power, and hence the *magnitude of variable capital*, could be taken as given as well. However, Marx (1988, 44) clarifies that although these elements can be taken provisionally as a 'known datum', the 'means of subsistence needed by the worker to live as a worker differ from one country to another and from one level of civilization to another'. Both the range of means of subsistence and the value of labour-power vary when one considers 'different epochs of the bourgeois period in the same country' (44). The systematic-dialectical investigation must therefore include an explanation of the dynamic principle of material transformation that presides over the changes in the value of labour-power. Those transformative dynamics can have no other source than the self-movement of capital in search of surplus value. Thus, a complete investigation of the value of labour-power should include the *internalisation and transformation* of its determinations as an *immanent* moment of the valorisation and expanded reproduction of capital. In other words, it should explore the implications of the *real* subsumption of labour to capital for the determination of the value of labour-power.

In *Capital*, Marx concentrated on the in-depth examination of the impact of the real subsumption on the value of labour-power mainly through the analysis of the associated changes in the *productivity of labour*. However, the same cannot be said of the 'the extent of the so-called primary requirements of life and the manner of their satisfaction', which also 'depend to a large degree on the level of civilization of the society' and are therefore 'the product of history' (Marx 1988, 44). In effect, although some elements for this investigation are scattered throughout *Capital*, Marx did not actually deal, in any systematic fashion, with the qualitative and quantitative determinations of the *changing patterns of consumption of the working class*. However, when all those loose threads are knit together, the main thrust of a coherent research programme can be formulated: such an investigation would need to search for the content of those determinations in the historically-changing forms of *productive subjectivity* of the differentiated organs of the collective labourer, in turn resulting from the material forms of the production of relative surplus value.

As we have seen, the process of individual consumption has no other content than the (re)production of the materiality of the productive subjectivity of wage-workers. Thus, as capital takes possession and modifies the labour process to produce relative surplus value, it transforms its requirements of qualitatively different physical and intellectual attributes that need to be set into motion to produce a mass of use-values 'pregnant' with surplus value. Moreover, it modifies accordingly the average normal combination of intensive and extensive magnitudes of the expenditure of labour-power in the direct process of production. In other words, with each cyclical renewal of the general technical basis of the valorisation process, capital revolutionises the productive subjectivity of the different organs of the collective labourer. *This transformation can only result from, and be reproduced by, the mutation of the 'norm of consumption' of the working class*.

Crucially, this transformation does not only involve the 'technical' component of the value of labour-power. The transformations of the capitalist labour process also entail the change in the aggregate of 'moral' attributes that must be set into motion under the new conditions of production and, therefore, novel 'requirements of life' and 'manners of their satisfaction'. In other words, historically-changing material bases of the valorisation process demand different concrete forms in which wage-workers must affirm their personal freedom in the process of production. And these different capacities also need to be reproduced through a changed pattern of consumption. Thus, as the productive subjectivity of wage-workers becomes progressively posited as the ever-purer result of the autonomised reproduction of the total social capital, the respective historical conditions of their genesis as free workers become increasingly residual for the determination of the value of labour-power. As capital undertakes the real subsumption of the labour process, it internalises the determination of the *moral* component of the value of labour-power as well, albeit in a distinct manner for the different types of labour-power that compose the collective labourer as a whole.

Indeed, as Marx (1976a, 469) himself acknowledges when discussing the *manufacturing division of labour*, the different degrees of complexity (hence of training) of the labour-power of each organ of the collective labourer entail differences in the value of labour-power. Yet, since in the chapter on *large-scale industry* Marx focuses on direct production work, he submits that those differences of skill tend to become eroded insofar as the system of machinery (gradually) leads to the expulsion of the intervention of the human hand and of experience-based practical knowledge of workers in the labour process. Large-scale industry is based on the objectification of *tacit* knowledge, previously embodied in the manual industrial worker and largely acquired through lengthy on-the-job, learning-by-doing processes, as an attribute of the system of machinery (Huws 2014). However, the benefit of historical hindsight allows us to recognise that there are other transformations of the collective labourer deriving from the increasing automation of the production process.

In the first place, the effect of increasing automation has not just been one of deskilling. It has been mixed – also entailing a certain creation of new skills that are required by capital even from direct production workers. For instance, the so-called 'microelectronic revolution' has entailed not only the degradation of the experience-based or *particularistic* dimension of direct production work but also the emergence and generalisation of so-called 'soft' or 'generic' skills (see Ramioul 2006), such as familiarity with computers and flexibility or individual initiative in problem-solving or decision-making (Balconi 2002). These newly created skills tend to revolve around the *universalistic* dimension of the productive quality of labour-power, whose development is achieved in the general process of education and socialisation that precedes its actual application in the production process.

Secondly, large-scale industry has also involved another tendency for the *expansion* of the productive attributes of the part of the collective labourer responsible for the advance in the conscious control of the movement of natural forces (i.e. science) and its technological applications in the direct social organisation of immediate production process. Although not explicitly addressed by Marx in *Capital* (but see 1976b, 1039–40), it is clear that the production of relative surplus value requires from these workers ever more *complex* forms of labour. As much as those discussed in *Capital*, these are also 'immediate effects of machine production on the worker' (see Starosta 2016, chapter 8).

Now, this divergence in the general kinds of productive subjectivity deriving from large-scale industry must be (re)produced through the difference in their respective 'norms of consumption'. This is *only partly* explained by the different degrees of training and education entailed by the expanded productive subjectivity of intellectual labourers. In our view, the development of the powers of scientific and/or 'creative' labour is undoubtedly also linked to a heightened sense of individual autonomy and independence, which defines, precisely, the historicity of the doubly-free labourer as a productive subject. Thus, the expansion of this type of intellectual labour has entailed the incorporation of certain use-values in the norm of consumption of this segment of the working class, which relate to the need to reinforce the concrete form of *personal* freedom through which their *objective* subjection to the *impersonal* power of capital subsists.

For instance, if we leave aside its overly apologetic overtone, the 'rational kernel' of much of the recent literature on the so-called 'creative class' speaks to these issues. Thus, scholars have noted the new lifestyles that have emerged in certain urban contexts populated by wage-labourers responsible for knowledge-based productive functions, which include a greater interest in 'extreme sports', in 'traveling to interesting, remote, and even risky locations' and, more generally, in 'experience-driven' consumption patterns (Florida 2012, 135). In our view, at stake in these forms of consumption is the reproduction of a form of productive subjectivity that sees itself as abstractly free and the affirmation of human individuality as the 'refusal of all constraints' to this 'natural' independence (whether from locality, natural forces, 'mainstream' society and culture, etc.).

Moreover, these changes have also been expressed in the manner of the appropriation of certain use-values. Crucially and emblematically, this can be seen in the use-value that is at the very core of the formation of the productive attributes of more complex forms of labour-power, namely: education. In effect, the need to stimulate creativity and independent thinking has led in recent decades to a growing emphasis on new pedagogical techniques like ‘student-centred’ learning, which precisely aims at the production of those kinds of attributes (creativity, initiative, etc.) by giving the student a more active role and greater individual responsibility in the learning process. Interestingly, this contrasts starkly with the kind of educational system prevailing in countries which are not at the vanguard of the development of the powers of intellectual labour and which have originally integrated in the so-called ‘New International Division of Labour’ as sources of cheap and disciplined simpler labour-power (Charnock and Starosta 2016). Thus, Grinberg (2011, 208) notes in his study of long-term capitalist development in Korea that ‘as late as 2007 the module “disciplined life” still formed part of the compulsory curriculum during the first 10 years of formal education’.

At this juncture, a final question obviously arises. For in this account of the determinations of the value of labour-power, and contrary to the ‘received wisdom’ of Marxists, the class struggle seems to play absolutely no part. It could seem that in order to access the means of subsistence that they need for the normal reproduction of their labour-power, they can safely leave the establishment of its value to the automatic operation of the ‘iron law of wages’. Unlike the establishment of a normal working day as explicitly discussed by Marx in chapter 10 of *Capital*, here there would be no need to ‘put their heads together as a class’. In the remaining two sections, we first show why this is not the case and, subsequently, we also illustrate the implications of this general discussion for the investigation of the concrete history of capitalist development.

Content and form of the determination of the value of labour-power: on the role of the class struggle

In contrast to the view outlined above, Marxists tend to conceive of the inner connection between the conditions of reproduction of labour-power and the material forms of its consumption in the capitalist production process as solely pertaining to the physical/technical component of the workers’ consumption. Regarding this part of the workers’ standard of living, they might not deny that it is *determined* by the material conditions of the direct production process of capital. However, all the means of subsistence which do not appear as immediately linked to the physical and technical reconstitution of labour-power, are seen as having no intrinsic connection whatsoever with the materiality of the capitalist labour process. The ‘historical and moral’ element is therefore rendered as *materially undetermined* and subject to the *contingent* result of the struggle between capitalists and workers.

The approach developed here leads to another view. More specifically, the material conditions of the reproduction process of capital constitute the *content* of the determination of the value of labour-power. They do so by determining the differentiated forms of productive subjectivity that compose the collective labourer and, as a consequence, the quantity and kind of means of subsistence that workers need to consume to reproduce those variegated qualitative attributes (both technical and moral) of labour-power. In turn, the class struggle becomes the necessary *form* that *mediates* the establishment of the material unity between the productive and consumptive requirements of the reproduction of the total social capital. Note, however, that the necessary mediating role of the class struggle in concretely *fixing* (as opposed to *determining*) the customary living standard of workers does not only apply to the historical and moral component. It pertains to the workers' consumption bundle *as a whole*, i.e. including the physical and technical elements. In other words, there is not a single use-value entering the determination of the value of labour-power, whose consumption is not *secured through* the struggle of wage-workers as a class. Conversely, the other side of the same coin is that there is not a single use-value consumed by wage-workers which is not *determined by* the material requirements of the valorisation process of the total social capital (which, it goes without saying, might clash with the immediate interest of individual capitals).

Furthermore, the relationship between the determination of the value of labour-power and its fixing by the class struggle is mediated by the wage-form. Thus, the level of wages expresses both the fluctuation of the rate of accumulation and of the magnitude of the 'reserve army' (Marx 1976a, 762–72). The acceleration (deceleration) of accumulation increases (decreases) the demand for labour-power and contracts (expands) the reserve army and thereby leads to a rise (fall) in the level of wages. However, in these oscillating movements of the wage, the value of labour-power (determined as explained above by the *normal* conditions of reproduction of the worker) does not change. Rather, through these recurrent cyclical deviations of the *price* of labour-power from its value-content (i.e. 'the norm'), the purchase of this peculiar commodity at its full value is, *on average*, achieved. On this score, the relationship between the wage and the value of labour-power is analogous to that of the price and value of 'ordinary' commodities. There are, however, two differences that set the commodity labour-power apart.

Firstly, as the above textual commentary on *Value, Price and Profit* showed, oscillations of the price of labour-power are necessarily channelled *politically* by the class struggle and do not result from the pure economic 'automatism' of 'market forces': the class struggle is strengthened (weakened) during the expansive (contractive) phase of the accumulation cycle (Marx 1992, 486–87). Secondly, under certain historical circumstances, the wage could stand consistently below the value of labour-power, i.e. beyond temporary crisis situations. This might happen in national spheres of valorisation of capital where there is a structural limit to the scale of the accumulation process and, consequently, there is a continuous growth of the relative surplus population *vis-à-vis* the needs of the expanded reproduction of capital. This explains why some countries have historically had a wage that has been remarkably lower than that prevailing in advanced capitalist countries, despite the similarity of productive attributes of the respective national working classes, as can be observed, for instance, in the automobile industry in Argentina *vis-à-vis* in the USA (Fitzsimons and Guevara 2016).

Now, this approach to the role of the class struggle in the determination of the value of labour-power is analogous to Marx's discussion of the length of the working day in *Capital*. As shown elsewhere, according to Marx's account class antagonism is not the self-determining process that contingently establishes the duration of the working day (Starosta 2016, chapter 7). By contrast, it is the *mediating social form* that forces the capitalist state to set legal limits to its extension beyond its *normal* length. However, the *content* of this normality is not undetermined, although it *appears* as such at first sight at the beginning of the presentation in the respective chapter. But as the exposition unfolds, it emerges that the normal duration of the working day is *materially-determined by* the conditions in which labour-power is consumed by capital in the process of production. A normal working day is therefore that which does not lead to the premature exhaustion of the reproduction of labour-power. The class struggle over the length of the working day thus gives shape to the payment of labour-power at its full value. It should be noted that, since at the systematic stage of chapter 10 the material forms of the labour process are an external presupposition *vis-à-vis* the self-movement of capital, Marx does not need to say much about the specific determinations that generate the necessity for the shortening of the working day beyond a general reference to overwork and premature exhaustion of labour-power caused by capital's 'voracious appetite for surplus labour'. However, as the systematic exposition progresses to the real subsumption of labour to capital, the material foundation of that alienated social necessity is brought to light: the shortening of the working day is the necessary concrete form taken by the increase of the *intensity* of labour that large-scale industry brings about (Marx 1976a, 536). In our view, it is the same with the amount and quality of means of consumption that enter into the reproduction of working class: the content is determined by the material forms of the production process, which is established (on average, through the cyclical oscillations of the wage) in the concrete form of the class struggle.

A brief illustration

In this section, we illustrate the originality and usefulness of our approach through a critical discussion of the more widespread explanations of the evolution of real wages through the so-called 'Fordist' cycle of accumulation in the US and Western Europe.

The highly-influential 'Regulationist' account revolves around the need to resolve the disequilibrium between sector I (that produces means of production) and sector II (that produces means of subsistence), in the context of an 'intensive regime of accumulation' that allegedly prevailed from the 1920s until the 1970s. In Aglietta's (2001) view, certain institutions (e.g. collective bargaining) regulated wage settlements so as to link them to productivity gains. This guaranteed that working-class consumption kept up with the rate of growth of output brought about by technical change, thereby creating the mass market needed to absorb the larger scales of mass production and so realise the surplus value.

This explanation has been strongly criticised in several ways by other scholars. In the first place, some authors have noted that the trends for the growth of productivity and wages can be traced back at least to the second half of the 19th century (Brenner and Glick 1991, 67–70, 82–83; Clarke 1988, 74–76), which calls into question the idea that wage increased during 'Fordism' to resolve imbalances between sectors I and II. Furthermore, the acceleration of wage increases that did occur took place during the inter-war period, i.e. *before* the establishment of the wage-regulating institutions that 'Regulationists' themselves situate in the 1950s. And Brenner and Glick (1991, 93) highlight that even during the post-war period (1948–1970) productivity increased at a faster pace than wages in the private industrial sector in the US. Finally, all these scholars have questioned the empirical evidence supporting claims about the existence of a 'social accord' that, allegedly, regulated wages.

Now, beyond their idiosyncrasies, these alternative explanations share the view that real wage increases did not respond to the needs of the accumulation of capital. Instead, they claim that they were the contingent result of a myriad of circumstances, among which the class struggle stands out (Brenner and Glick 1991, 93; Clarke 1988, 85–86; Mavroudeas 2003, 244–45). However, we think that this does not provide solid grounds to account for the undeniable long-term trend for rising real wages that has accompanied the development of large-scale industry in all advanced capitalist countries at least until the 1970s. In effect, it would be rather surprising that the 'unplanned outcome of myriad uncoordinated private decisions by firms about prices and myriad employer-labour conflicts over the terms of employment' (Brenner and Glick 1991, 93) yielded the same results everywhere and during such a long time-frame, without an underlying 'structural' tendency. In other words, the very intensification of the class struggle that was the *immediate cause* behind wage increases *also* needs to be explained.

From our perspective, the key resides in the effects of the real subsumption of labour on the productive attributes of wage-workers. This provided the material basis or content of the increased political strength of the working class in its struggle over the conditions of reproduction of their labour-power. In fact, Aglietta (2001, 158–59) himself identifies (albeit just in passing) one of the determinants of real wage increases (hence of the enlargement of the consumption basket of wage-workers): the need to compensate for the greater expenditure of labour-power derived from the increase in the intensity of labour brought about by the development of the system of machinery. However, we think that this is only part of the story.

As argued above, the evolution of large-scale industry entailed the expansion of the productive attributes of wage-workers responsible for complex intellectual and scientific labour. Moreover, the relative weight of this organ of the collective labourer in advanced capitalist countries grew consistently throughout the 20th century, expressed both in the growing importance of R&D labour and in the expansion of 'white collar' work involved in the organisation and planning of large-scale industrial productions (and also in the larger civil service as the activities of the capitalist state expanded). This expansion of their productive subjectivity took shape not only through the lengthening of the years of formal education (which, incidentally, also included direct production workers) but also through the extension of the productive life time of wage-workers (so that capital could extend the years of their exploitation to compensate for the longer time involved in the production of their more complex labour-power). Hence, the very reproduction of capital demanded the widening of the 'norm of consumption' to include, among others, a whole series of use-values linked to education and health. Moreover, intellectual labour entails a greater intensity (due to heightened focus and attention) that also needs the shortening of the working day. Finally, in addition to those aspects that relate to the physical or technical (re)production of the more complex forms of labour-power, other use-values eventually entered the 'norm of consumption' in order to reproduce what we have termed the moral productive attributes of wage-workers, i.e. those that fostered the appearance of abstractly-free individuality through which their subsumption to capital is realised. It is no wonder that this is the period of the proliferation of the so-called 'culture industries', which not only played an ideological role as most critical accounts of its emergence tend to posit but were also necessary for the reproduction of the productive attributes of doubly-free labour, both their moral component and even their technical aspect. Indeed, the consumption of certain 'cultural' use-values can be materially necessary for the reproduction of the capacity for abstract thinking involved in intellectual labour (e.g. 'art-house' films or 'experimental' music).

In sum, all these determinations meant that real wages tended to rise, thereby *partly* offsetting the productivity increases in search of relative surplus value. These dynamics had their material foundation in the changes in the capitalist labour process and the associated transformations of the productive subjectivity of wage-labourers. These could only be (re)produced through novel forms and expanded levels of consumption, which, in turn, could only be achieved in the concrete form of the struggle of wage-labourers as a class.

Conclusion

This chapter has critically examined what we see as the 'received wisdom' on the determination of the value of labour-power. Even if with variations on the same theme, this virtually universal consensus among Marxists considers that the class struggle *determines* to some extent the value of labour-power. This determination is seen as taking place through the part played by the class struggle in the actual definition of the content of the 'historical and moral' element of wage-workers' consumption. As we have seen, this perspective is ridden both with exegetical problems as a reading of Marx and, more importantly, with theoretical weaknesses concerning its capacity to offer a sound materialistic explanation of the determination of the value of labour-power.

In contrast to this received wisdom, we offered an alternative reading of Marx's explanation of the determinants of the value of labour-power which, we think, manages to overcome the pitfalls of the former. This rethinking of the value of labour-power rests on two key insights that we developed above. A first more substantive issue concerns the actual meaning and significance of the so-called 'historical and moral' component of the value of labour-power. In our view, this element does not condense, as is usually assumed among Marxists, the balance of class forces. Instead, it must be rethought as involving the historically-changing concrete forms taken by the personally-free *productive* subjectivity of the wage-worker, i.e. as comprising what we termed the 'moral productive attributes' of wage-workers. The latter are a material aspect of labour-power exploited by capital as any other technical ability in a restricted sense and, for this reason, are fully determined by the material configuration of the capitalist labour process as well.

The second key point that we made had a more general methodological significance. In a nutshell, it pertained to the unity and difference between the *content* of a certain determination and its concrete *form of realisation*. Specifically in connection to the determination of the value of labour-power, we argued for the need to clearly distinguish between the content of that process of determination, which derives from the material requirements of capital's production of relative surplus value, and its necessary mode of realisation *through* the class struggle, which concretely secures that, *on average*, labour-power trades at its full value (including *both* the 'physical' and 'moral' components).

Admittedly, our discussion has offered a first approximation to the relationship between working-class consumption, the (re)production of their productive attributes and the determination of the value of labour-power. More strictly put, the chapter just developed the simpler or more general aspects of the subject matter. However, we think that these ideas can provide a firmer starting point and methodological blueprint for the much-needed research into the forms in which capital historically transforms the productive subjectivity of wage-workers.

6 Extra surplus value from innovation and the Marxian critique of political economy

Introduction

In his exposition of the production of relative surplus value, Marx points out that before the generalisation of a certain technical innovation, innovating capitals appropriate an 'extra surplus value'. In quantitative terms, this surplus value is determined by the divergence between the 'individual value' of commodities produced by early innovators and the price at which all commodities from the respective branch of production are sold, which in turn must stand below the 'old social value' (Marx 1976, 433–36). In effect, individual commodities produced with the more advanced method of production resulting from technological change contain less labour than those which were produced with the old technique. In light of Marx's argument that (privately-performed) socially necessary abstract labour constitutes the substance of value (Marx 1976, 125ff.; Starosta 2008), the question arises as to which labour constitutes the substance of the extra surplus value appropriated by early innovating capitals.

The traditional answer to this question tended to state, albeit implicitly and rather unreflectively, that the appropriation of this extra surplus value by early innovators implied, as happens with every kind of surplus profit, a redistribution of surplus value extracted from wage-workers by other capitals. However, this claim does not quite identify the specific source of the extra surplus value. In other words, it falls short of specifying the individual capitals from which the original surplus value which ends up in the pockets of early innovators comes from. Furthermore, the traditional approach does not clarify the mediating concrete forms through which the said surplus value flows between capitals. More importantly, it does not explicitly respond to the alternative view that can be found in the specialised literature, which claims that the extra surplus value is the social representation of the labour extracted from the wage-workers exploited by innovating capitals themselves. Paraphrasing Marx's (1976, 90) words in the preface to the first edition of *Capital*, the search for the specific source of extra surplus value 'seems to turn upon minutiae'. Yet, as we hope to make evident in this chapter, this issue has implicitly underpinned several important Marxist debates in diverse intellectual and historical contexts.

DOI: 10.4324/9781003201939-7

Against this background, the first aim of this chapter is to bring to the fore this debate over the source of extra surplus value from technical innovations, which so far has remained subsidiary to other controversies, as a theoretical problematic in its own right. We shall therefore delineate the different polemics and perspectives which have addressed this issue and sketch out the main arguments put forward in each of them. In the second place, insofar as a great deal of the literature has revolved around the discussion of the pages from Volume I of *Capital* which address this question, a further aim of this chapter is to examine those passages in the light of the broader textual evidence than can be gathered from the rest of Marx's economic works. Finally, we shall offer a brief critical assessment of the debate with a view to throwing into relief the more general theoretical issues in Marxian value theory which, we think, underpin the more concrete determinations of extra surplus value from technical innovations.

The debate over extra surplus value as subsidiary to other Marxist controversies

Historically, the debate over the source of extra surplus value can be traced back to the Japanese controversy over the theory of ground-rent, which emerged before the Second World War. As Itoh (1988, 240) reports, the idea that the extra surplus value represents the objectified labour extracted by the innovating capital was the basis of the theoretical position of Kōza-ha scholars, as argued, for instance, in the writings of Yamada (1948, cited by Itoh, 1988). These were the grounds on which they attempted to defend the Soviet orthodox view that differential ground-rent was the product of agrarian workers and did not constitute surplus value transferred from the industrial sector. By contrast, Rōnō-ha scholars and, later, those of the Uno school, maintained that the extra surplus value was a cost paid by society as a whole, so that ground-rent should be grasped as a deduction from the total social surplus value which was captured by landowners. This alternative perspective can be traced back to Sakisaka (1930) and Susuki (1952), both cited by Itoh (1988), and is also Uno's (1977, 94n10) own position. Subsequently, it was further developed by Uno's most prominent disciples, like Itoh (1980, 92; 1988, 144–45, 226–43) and Sekine (1997a, 144–46; 1997b, 42–51; 2020, 250, 436).

The question resurfaced in the 1970s in the German controversy over the status of the 'law of value and the world market'. In this different context, the view that states that extra surplus value originates in the labour performed by workers exploited by the innovating capital served to support the argument that the operation of the 'law of value' experienced modifications when conceptualised at the level of the world market: the higher productivity of labour in a certain country involves the production of more value per unit of time *vis-à-vis* those countries which operate with a lower productivity of labour. The most salient contributions in this regard were those by Busch et al. (1971, 21–24), Neusüss (1972, 115–19) and Schoeller (1973, 104–7). In turn, Mandel's (1976, 92–107, 350–51) intervention in this controversy played the part of transmission belt which ramified this discussion into that which revolves around the so-called ‘unequal exchange’ between ‘developed’ or ‘central’ countries and ‘underdeveloped’ or ‘peripheral’ ones. More specifically, the question at stake in this other polemic was whether this hierarchical polarisation of the global economy can be explained on the basis of international transfers of value that underpin the exchange of commodities on the capitalist world market. Among the numerous scholars from all over the world that have contributed to this issue, the following can be mentioned for having explicitly brought up the question of extra surplus value: Marini (1979a; 1979b; 2022, 121ff.), Shaikh (1980), Siegel (1984), Astarita (2006, 273–305; 2010, 58–60), Borges Neto (2011), Nieto Fernández (2015, 209–21), Féliz (2021). On the other hand, some contributions explicitly incorporated arguments that had been advanced in the aforementioned German ‘world market debate’. This is the case of Carchedi (1991a), Milios and Sotiropoulos (2009, 243–54) and Sandleben (2016).

Some authors also resorted to the argument that the source of the extra surplus value resides in the labour of workers exploited by the innovating capital in the context of the so-called ‘transformation problem’. In a nutshell, these works claim that in the same way as the appropriation of an extra surplus value by the early innovator does not involve any transfer of surplus value from other individual capitals, the appropriation of the normal or average rate of profit does not entail any redistribution of surplus value across different branches of production. Consequently, this line of reasoning continues, the ‘transformation problem’ is free from the alleged inconsistencies in the quantitative relations between total surplus value and aggregate profits. The main contributions that have argued along these lines are: Martínez Marzoa (1983, 66–77), Nieto Fernández (2015, 151–72), Reuten (2017; 2018; 2019), and, in a very similar approach, Robles Báez (2001; 2011, 137–52). In turn, these idiosyncratic takes on the ‘transformation problem’ have elicited dedicated responses and comments. Thus, Fernández Liria and Alegre Zahonero (2010, 547–96) have engaged with Martínez Marzoa’s work, whilst Arthur (2018) has provided a sympathetic criticism of Reuten’s contribution.

The determinations of extra surplus value have also been implicit in Latin American Marxist polemics over the source of surplus value that constitutes ground-rent. This literature can be traced back to the 1970s (Bartra 1979; Laclau 1969, among others). Albeit inadvertently, the different substantive positions in this controversy replicate the two opposing camps that had consolidated in the analogous Japanese debate mentioned earlier on. However, in this novel regional and intellectual context, the substantive issue of the general nature of (differential) ground-rent was taken to bear on the international economic relations between ‘centre’ and ‘periphery’. More specifically, according to one of the main positions in this debate, the ground-rent incorporated in commodities exported from Latin American economies had its source in the surplus value produced by workers from importing (i.e. ‘central’) countries. As some interventions in this debate explicitly noted, this discussion evidently dovetails with that on the role of extra surplus value in unequal exchange. This Latin American discussion cropped up again in more recent times, but now with more explicit attention to the question of extra surplus value: Arceo (2003, 83ff.), Astarita (2010, 197–200, 221–23), Foladori (2013), and Iñigo Carrera (2017, 85–104, 194–207).

As reported in Jeon (2011; 2015), the source of extra surplus value has also played an important role in the recent Korean debate on the substance of value of so-called ‘cognitive commodities’. In this intellectual context, one of the central themes under discussion has been the compatibility between the ‘law of value’ and ‘knowledge-intensive’ commodities, for which the costs of reproduction are virtually insignificant, whilst there is no price differential between the first unit produced and the rest of the output (software being the paradigmatic case in point). Against this backdrop, the argument that extra surplus value from innovation originates from the labour set into motion by innovating capitals precisely served as an attempt to establish the consistency between this feature of contemporary ‘Cognitive Capitalism’ and the ‘law of value’. According to some of this literature, individual capitals specialised in the production of ‘cognitive commodities’ should be considered as early innovators as far as the source of their surplus profits is concerned (Fine, Jeon, and Gimm 2010; Jeon 2010; 2015).

Although probably in a more tangential manner, the main theme of this chapter has been somehow present in at least two additional important Marxist debates: that on ‘complex or skilled labour’ and that on ‘socially necessary labour’. In the former case, the alleged connection between a higher productivity of labour and multiplied *value-creating* powers of labour has been used to explain the comparatively higher value of the products of complex or skilled labour *vis-à-vis* those of simple labour. This train of thought thus constitutes one of the contemporary ‘solutions’ to the skilled labour ‘reduction problem’ (see Chapter 4). In the case of the debate on ‘socially necessary labour’, the question of value transfers derived from productivity differentials among individual capitals has been one of the fundamental controversial issues at stake. In this context, the increasingly hegemonic perspective considers that the source of extra surplus value (or surplus profits) pocketed by the early innovator is the labour of wage-workers exploited by *other* individual capitals (Carchedi 1991b, 56–68; Horverak 1988; Indart 1987; Itoh 1980, 80–92; 1988, 226–35; Itoh and Yokokawa 2015; Kristjanson-Gural 2003; Lee 1998; Sekine 1982; Shaikh 1990, among others).

Lastly, mention should be made of a few works that have focused on the source of extra surplus value as a theoretical problem in its own right. This is the case, for instance, of Echeverría (1986, 128–36), Tomba (2013, 138–44) and Veraza (2017, 259ff.). Still, they have not explicitly framed their treatment of this question against the background of the wider intellectual controversy which, as we have attempted to show, has surrounded this problematic. It has been only in Brazil, in the past 20 years, where the problem of extra surplus value has been addressed more systematically and deliberately carried out in the form of an academic intellectual dispute (Borges Neto 2001; Carcanholo 2013, 103–17; Cipolla 2003; 2002, 207ff.; Lagoeiro de Magalhães 2004). The debate, however, involved only a limited number of scholars and remained within the local milieu, without virtually any impact on the international discussion.

The main arguments in the debate

The 'potentiated labour' thesis

There are two principal arguments that cut across practically all interventions in favour of this view. The first one is of an eminently philological nature and revolves around an idiosyncratic reading of the following passage from the chapter of Volume I of *Capital* in which Marx explicitly addresses the question of extra surplus value from innovation: 'The exceptionally productive labour acts as potentiated labour; it creates in equal periods of time greater value than average social labour of the same kind' (Marx 1976, 435, translation amended).[1] According to this reading, in this passage, Marx would be stating that the labour that the early innovator sets into motion must be considered as 'potentiated labour', whose very definition entails that it creates more value per unit of time than average social labour; in the same vein as complex or skilled labour produces more value than simple labour in the same period of time (Marx 1976, 135). This interpretation implies that the labour set into motion by innovating capitals produces more value than that which is employed by those which have not yet incorporated the new method of production. Thus, the substance or source of the extra surplus value pocketed by the early innovator must be this 'potentiated labour'. No value transfers are needed to account for the existence of extra surplus value.

The second fundamental argument builds on the first one but is more substantive. It states that only in this way can the extra surplus value be grasped as an expression of a reified social relation. The reason for this is that this view considers, in a clearly 'circulationist' take on value as a historically-specific social form, that the latter only comes effectively into being through the exchange of commodities. Put differently, according to this perspective, abstract labour, which constitutes the substance of value, acquires real, practical objective existence only in the circulation process, which is where an effective social relation between persons is established. Conversely, the contrasting view, which claims that the extra surplus value originates in the labour exploited by non-innovating capitals, is said to lapse into a 'technological' conception of value that overlooks the specific social form of value-producing labour. Value would be thus conceptualised as the simple objectification of the *concrete* labour-time materially expended in production (since, as we have seen, according to the circulationist leanings of the 'potentiated labour' thesis, abstract labour can only come into being through exchange). In a nutshell, the explanation of extra surplus value based on value transfers among individual capitals is seen as necessarily involving a 'Ricardian retrogression' which naturalises capitalist social relations.

Building on these two conceptual pillars, different contributions to the 'potentiated labour' thesis offer further particular arguments to support this view. The first group of theorists focuses on the general determination of the value of commodities. They argue that what counts as socially necessary labour is just that amount of social labour expended in a determinate branch of production which society is willing to recognise through exchange. This means that the magnitude of value does not correspond to the privately-performed material expenditure of social labour in production, but only to that part which is socially validated in the circulation process (Busch et al. 1971, 20ff.; Veraza 2017, 265ff.). In a similar vein, other scholars submit that abstract labour can only be measured in circulation, so that the magnitude of value must be determined in that sphere. More concretely, these authors consider that the circulation process is the phase which effectuates the 'normalisation of individual labours' which, in turn, reduces their material differences by imposing their social unity as abstract labour (Borges Neto 2001; 2002, 124–32, 207ff.). This train of thought is pushed further forward through the notion that abstract labour's effective constitution only takes place as an 'inter-branch social average'. Thus, the argument goes, the reduction of the diversity of concrete labours to abstract labour within a branch of production already involves the formation of the general rate of profit and, therefore, the development of the respective prices in the form of prices of production. It follows that it is meaningless to even pose the question of value transfers, whether within or between branches of the social division of labour. *A fortiori*, it makes no sense to explain the source of extra surplus value in terms of the early innovator's appropriation of surplus value originally produced elsewhere (Martínez Marzoa 1983, 66ff.; Nieto Fernández 2015, 166ff.). A similar argument can be found in other contributions which conceive of the constitution of prices of production as the systematic 'moment' which establishes the actual quantitative determination of commodities' values (Reuten 2017; 2018; 2019; Robles Báez 2001; 2011, 137–52).

Another group of contributions approach the issue from a methodological angle rather than in substantive terms. These arguments tend to revolve around the problematisation of the systematic place of Marx's account of extra surplus value in the expositional structure of the three volumes of *Capital*. Thus, it is claimed that insofar as Marx discusses extra surplus value from innovation in Volume I and, furthermore, that the latter deals with the direct production process of capital, the former cannot derive from the inter-branch transfer of surplus value through exchange but must necessarily originate in the production process. As a matter of fact, the treatment of value transfers belongs, in systematic terms, in Volume III, which precisely deals with the concrete forms in which the overall unity of the social production process is established. More specifically, it is only in the third volume that Marx introduces the categories of 'profit' and 'surplus profits' to refer to the phenomenal forms respectively assumed by 'surplus value' and 'extra surplus value'. Moreover, insofar as those phenomenal concrete forms involve quantitative differences from their content, these contributions conclude that only at that stage can the very possibility of value transfers be raised (as happens, for instance, with the formation of the general rate of profit). The implication that some of these authors draw is that had Marx considered that the determinations of extra surplus value involve value transfers, he would have bracketed the question until Volume III. The fact that he did not is seen as a further testament to the incorrectness of the 'value transfer' thesis (Veraza 2017, 250–63).

Another methodological argument advanced aims at establishing the consistency between the 'potentiated labour' thesis and the Marxian opening lines on the quantitative determination of the magnitude of value in chapter 1 of Volume I of *Capital*, according to which 'the greater the productivity of labour, the less the labour-time required to produce and article […] and the less its value' (Marx 1976, 131). On the face of it, this passage seems to stand in blatant contradiction with the 'potentiated labour' thesis' reading of chapter 12 of Volume I, which claims that more productive labour creates more value in the production process in equal periods of time. However, it is argued in this literature that the two passages correspond to different levels of abstraction. The former statement, according to which a greater productivity of labour is expressed in a lower value of individual commodities, corresponds to the analysis of a single individual capital, in which, by definition, individual and social value coincide. By contrast, the latter claim corresponds to the analysis of the movement of competition between multiple individual capitals, in which the determination of value changes. In turn, it is argued that it is essential to distinguish between diachronic and synchronic analysis, whereby the former deals with the generation of *more* value and the latter with *less* (Nieto Fernández 2015, 160–66).

The 'value transfer' thesis

Most critical responses to the 'potentiated labour' thesis resort to two related fundamental arguments. In the first place, they emphasise that, by definition, an increase in the productivity of labour does not generate more value but more *use-values*, each of which is the material bearer of a lower quantity of value. In other words, this first objection claims that the 'potentiated labour' thesis is quite simply inconsistent with the Marxian explanation of the determination of value. In the second place, scholars from this other camp point out that the 'potentiated labour' thesis tears apart the quantitative identity between the socially necessary labour performed in production by wage-workers as a whole and the total value realised in circulation (some authors specify this further and focus their attention on the quantitative identity between total surplus labour and total surplus value). The reason for this is that according to the logic of the 'potentiated labour' thesis, the existence of an extra surplus value necessarily entails the increase in the total mass of value realised in circulation, whilst the total amount of socially necessary labour expended in production across society remains constant. By contrast, these critics highlight that the Marxian explanation of the value-determinations presupposes the aggregate equality between the total amount of privately-performed socially necessary abstract labour and the mass of value available across society. Thus, the appropriation of an extra surplus value by some capitals can only have its substance in the exploitation of labour undertaken by other individual capitals.

Analogously to the other camp in the debate, this other literature develops further particular arguments on these two general grounds. A first set of discussions point to the identification of the determinate capitals that cede the surplus value that constitutes the source of the extra surplus value appropriated by early innovators. In a first analytical step, this literature usually considers that the expansion of the number of commodities that reach the market following the increase in the productivity of labour, faces a given solvent demand in monetary terms. In this scenario, the resulting fall in the unitary selling price of each commodity necessarily means that the aggregate loss of surplus value by non-innovating capitals matches the amount of extra surplus value appropriated by early innovators. In other words, since the total mass of value appropriated in the respective branch of production remained unaltered whilst total output increased, losses and gains of surplus value must offset each other. Thus, under these circumstances, the source or substance of the extra surplus value resides in the loss of surplus value of non-innovating capitals from the same branch (Carcanholo 2013, 111–13; Carchedi 1991b, 65–68; Echeverría 1986, 133–34; Iñigo Carrera 2017, 93–94; Sekine 1997a, 144–46).

In a second analytical step, these contributions consider the case in which the extent of the fall in the unitary selling price of the respective commodities leads to an *expansion* of the aggregate monetary effective demand for them. In this alternative scenario, the source of extra surplus value is not limited to the losses of non-innovating capitals from the same branch of production but extends to those suffered by capitals operating in other branches of the social division of labour. This cross-branch flow of surplus value is mediated by the purchase of the aggregate output of the branch in which the technical innovation took place, at a sum of prices which stands above the mass of value corresponding to the total labour-time expended in that branch of production (conversely, commodities produced by those capitals from other branches experience a corresponding drop in aggregate solvent monetary demand, which leads to a fall of the unitary selling price below the social value). Some works in this literature, which incorporate Marxian insights from chapter 10 of Volume III in the treatment of the problematic of extra surplus value, and consider the moving trajectory of the *social or market value* between the initial introduction and the eventual generalisation of the new method of production, stress that, in this second scenario, the expansion of effective monetary demand leads to a temporary divergence between the social value and the selling *market price*.[2] Furthermore, and unlike the first case, insofar as part of the extra surplus value appropriated by early innovators does not have its substance in the social labour expended in *production* within the respective branch, but flows into their pockets from other branches and purely through the *circulation* process, some authors conclude that this latter portion of monetary social wealth constitutes *surplus profits* rather than extra surplus value 'proper' (i.e. a category of circulation rather than production). Works within this broad literature which develop numerical examples include: Carcanholo (2013, 112ff.), Cipolla (2003, 99ff.) and Iñigo Carrera (2017, 94ff.). The general theoretical discussion is systematically presented in Itoh and Yokokawa (2015) and Itoh (1988, 226–35).

In addition to these substantive arguments, these contributions also approach the question with methodological lenses. They thus thematise the problematic of extra surplus value in terms of its systematic place in the presentational architecture of the three volumes of *Capital*. The main argument in this regard is to emphasise that the first volume deals with 'capital in general', whilst Volume III approaches the 'configurations of capital' springing from 'the action of different capitals on one another, i.e. in competition' (Marx 1991a, 117). Methodologically speaking, this means that the treatment of extra surplus value does not properly correspond to the level of abstraction of Volume I but to Volume III. More specifically, this issue belongs in the chapter dealing with the competition process that equalises the rate of profit through the establishment of market prices regulated by prices of production. Seen in this light, these authors conclude, it becomes evident that at stake here is the 'redistribution of surplus value' in the fetishised and inverted concrete forms springing from circulation through the competition process (Carcanholo 2013, 110–17; Cipolla 2003, 89ff.; Iñigo Carrera 2017, 196ff.; Mandel 1976, 94–102). As for Marx's own methodological decision to 'bring forward' the discussion of extra surplus value to chapter 12 of Volume I, it is argued that it would have been a 'pedagogically-minded' presentational strategy to facilitate a 'better understanding of relative surplus value' (Carcanholo 2013, 110). Along the same lines, other scholars maintain that the 'potentiated labour' thesis is inconsistent with Marx's explanation in chapter 10 of Volume III, according to which the social or market value is formed on the basis of individual values (Cipolla 2003, 99). Lastly, many contributions object to the 'potentiated labour' thesis that it postulates an *immediate identity* between *extra* surplus value and *relative* surplus value, whose essentially *spurious* character is evidenced once we consider that, as soon as the new method of production becomes generalised in the respective branch of production, the former disappears whilst the latter comes effectively into being (Itoh 1988, 145; Sekine 1997a, 146; Uno 1977, 94n10). In a nutshell, all these methodologically-minded arguments point to the conceptual confusion between different levels of abstraction that they find in the 'potentiated labour' thesis.

Marx on the source of extra surplus value

Our discussion in the previous section makes evident that the controversy has revolved to a large extent around Marx's own views on the determinations of extra surplus value, whether simply on the basis of textual evidence or on the overall consistency between Marx's writings on this specific issue and the rest of his works. Consequently, the further reconstruction of the main aspects of the Marxist debate on extra surplus value requires that we now turn to systematise and examine more closely the different texts in which Marx approached this question. At this juncture, it is important to emphasise that it is far from our aim to offer a 'definitive interpretation' of Marx's thought on the subject, as many readings somehow naively have intended to do. In this sense, it goes without saying that, from a philological perspective, a text or set of them can admit more than one plausible reading. More importantly, even if it were possible to come up with just one coherent reading, this would not suffice to settle the controversy. At most, we would have a more (or less) firmly grounded appeal to authority. Instead, as intended in our exploration of the different arguments in the Marxist debate, the point here is to offer some philological elements which can contribute to a critical reconstruction of the determinations of the source of extra surplus value.

At first sight, the passage from chapter 12 of Volume I of *Capital* that we cited earlier might seem an irrefutable piece of textual evidence in favour of the 'potentiated labour' thesis that would make all controversy otiose. Indeed, this is the way in which authors from this camp tend to address that text which, it must be duly acknowledged, has been revised and edited by Marx himself and constitutes his latest written passage on this problematic. Moreover, also in that chapter, Marx (1976, 435) adds that even in the case of extra surplus value 'the increased production of surplus value arises from the curtailment of necessary labour time, and the corresponding prolongation of the surplus labour'. In other words, he seems to consider the production of *extra* surplus value analogously to its *normal* form. Additionally, a similar formulation can be found in chapter 15 of Volume I on 'Machinery and Large-Scale Industry' (530).

On the other hand, it is worth noting that Marx's numerical example in chapter 12 of Volume I does *not* include any reference to the situation of non-innovating capitals (i.e. whether they suffer any loss of surplus value). Lastly, also in support of the 'potentiated labour' reading, there are various passages in Marx's preparatory manuscripts which, at least taken at face value, do not seem blatantly to clash with the passage from chapter 12 of Volume I that triggered the whole polemic (Marx 1988, 238–41, 319–20, 327–30, 336–37; 1989a, 430; 1989b, 254–440; 1991b, 126–30, 147–49).

Yet, as some of the contributions to the competing thesis have indicated, Marx's formulation in the said passage is very far from unequivocal (Carcanholo 2013, 110–11; Iñigo Carrera 2017, 197–98). First and foremost, in this text, Marx does not say that the exceptionally productive labour *is* or *turns out to be* 'potentiated labour', but that it *acts as* such ('*wirkt als*' in the German original). This kind of phrasing can most certainly be read in terms of the establishment of an *analogy* with potentiated labour, rather than simply *identifying* more productive labour with it. Additionally, that text does not claim that the latter generates 'more value', which is the unequivocal formulation which Marx consistently uses when referring to a genuine case of an increase in the magnitude of value of an individual commodity. Instead, it somehow enigmatically says that it creates 'greater *values*' (*höhere Werthe* in the German original). Here it is worth noticing that these German terms are not used very frequently in Marx's economic works. More remarkably, he tends to use the term 'values' (*Werthe*) not as a synonym with 'sums of value' but of 'commodities', i.e. unities of use-value and value (Marx 1976, 166–67, 172). Thus, the phrase under polemic could as well be read as meaning that the exceptionally productive labour generates more 'commodities', which is a fact beyond dispute.

Now, in light of these ambiguities in Marx's 'canonical' passage on extra surplus value, we think that it is imperative to examine the other textual evidence from his writings on the subject, a task which is usually sidestepped by supporters of the 'potentiated labour' thesis. In this sense, the following points must be borne in mind.

In the first place, there are various instances in which Marx refers to the same case of differences in the degree of productivity of labour but in the context of the world market. And as long as in this global context there are barriers to the international mobility of capital (a fact which is not an absolute unchanging circumstance but an expression of an insufficient development of the capitalist mode of production), commodities produced with an exceptionally productive labour will exchange on the world market 'as if' they were the materialisation of a greater quantity of social labour. Here it is interesting to note that Marx's use of similar expressions to 'acts as' systematically recurs in several of these passages. Moreover, he does not refer to 'potentiated labour' but, alternatively, to 'stand above', 'more complex', 'higher specific weight' or 'more intensive'. This calls into question the all too easy assumption that Marx meant the term 'potentiated labour' in its precise theoretical sense, i.e. as labour with multiplied 'value-producing' powers. Instead, it seems to suggest the opposite reading, namely, that when referring to more productive labour as 'potentiated labour', he was more likely reasoning through *analogy* (Marx 1976, 702; 1988, 338; 1989b, 294; 1991a, 344–45).[3]

In the second place, it is important to bear in mind that Marx's various references to the question of extra surplus value scattered over Marx's economic works are usually brief in-passing reflections, mostly external digressions which do not correspond to the dialectical-systematic moment of the immediate object under consideration at those stages. In this sense, one of the richest and most illustrative texts in this regard is the methodological remark that prefaces the 'canonical' polemic passage on extra surplus value in chapter 12 of Volume I:

> it is not our intention here to consider the way in which the immanent laws of capitalist production manifest themselves in the external movement of the individual capitals, assert themselves as the coercive laws of competition, […] Nevertheless, for the understanding of the production of relative surplus-value, and merely on the basis of the results already achieved, we may add the following remarks.
>
> (Marx 1976, 433)

In a nutshell, as some of the contributions to the debate have rightly emphasised, this quote suggests that, *strictu sensu*, the problematic of extra surplus value does not belong in Volume I but in a later systematic-dialectical stage; more precisely, when unfolding the more concrete determinations of competition in Volume III. Additionally, it implies that whatever Marx said about the subject matter in chapter 12 of Volume I, he could not incorporate all the determinations at play in the said phenomenon. In other words, as perceptively indicated by Carcanholo (2013, 109–10), Marx's remarks were able to throw into relief *only* those aspects of extra surplus value which could be addressed 'merely on the basis of the results already achieved', i.e. *at that particular stage of the dialectical exposition*. This calls into question the aforementioned argument by the 'potentiated labour' thesis proponents, which claims that the source of extra surplus value must be the labour exploited by the innovating capital because Marx placed the exposition of the subject in Volume I, which deals with the process of *production* of capital. More broadly, it puts Marx's own treatment of the subject in chapter 12 into perspective. As explicitly acknowledged by Marx himself in the passage just quoted, its aim and scope are self-consciously limited, so the profundity and precision of his analysis should not be overstated.

It follows from this that a fuller picture of the Marx's view of the determinations of extra surplus value, must necessarily incorporate additional elements from the text in which he effectively addressed the competition process among multiple individual capitals as the focus of his exposition, which is in chapter 10 of Volume III. In this more concrete context, the first remarkable point to mention is that there seems to be no doubt that, in these pages, Marx considers that the 'surplus profits' appropriated by those capitals which set into motion a higher productivity of labour originates in the surplus value that escapes the pockets of *other* individual capitals with a lower labour productivity, i.e. it involves a 'value transfer'. As a matter of fact, we have seen that this is the prevailing view in the debate over 'socially necessary labour' which largely revolves around the discussion of these pages of Volume III. What is more, even proponents of the 'potentiated labour' thesis concede that the term 'surplus profits' entails transfers of value. The following passage, found both in Marx's original *1864–1865 Manuscripts* and in Engels's edition of the third volume of *Capital*, is probably one of the most eloquent in this regard:

> the commodities whose *individual* value stands below the *market price* will realise a *surplus-profit*, i.e., more value, while those whose *individual value* stands above the market price will be unable to realise a part of the surplus-value which they contain.
>
> (Marx 1991a, 279, emphasis added; see similar passages in Marx 2015, 279–80, 284–85)[4]

It seems clear from this quote that the other side of the realisation of a surplus profit on the part of certain commodities lies in the incapacity of others to realise a portion of the surplus value '*contained*' in them. This has already been noted in the 'value transfer' literature in Mandel (1976, 101), whilst Itoh and Yokokawa (2015) and Itoh (1988, 230ff.) provide additional analogous textual evidence from the same chapter. More substantively, it gives firmer support to the 'value transfer' thesis, at least in the narrower version which is limited to intra-branch flows of surplus value. On the other hand, it strongly challenges the 'circulationist' strand of argument in the 'potentiated labour' thesis reviewed in a previous section, which states that the qualitative and quantitative determination of (surplus) value effectively takes place in the exchange process.

In sum, the first conclusion that can be drawn from this discussion is that the term 'extra surplus value' that Marx introduced in Volume I of *Capital*, was the way that he came up with to refer to 'surplus profits' in a systematic-dialectical level of abstraction in which he could not yet deploy the latter terminology, which pertained to more concrete phenomenal forms of the movement of the overall process of production of capital. Likewise, it seems reasonable to conclude that both the analogy with potentiated labour and the limited scope of the numerical example in chapter 12 of Volume I that Marx developed to illustrate the explanation of extra surplus value, followed the same methodological tenet that prevented the unfolding of the movements of surplus value that spring from the more concrete forms taken by the competition among individual capitals.

On a final note, this reading offers novel elements to make sense of the contrast that Marx (1989b, 88, 470; 1991a, 300–1, 429–30, 780ff.) recurringly makes between surplus profits from an exceptional productivity of labour and the phenomenon of differential ground-rent. Specifically, the only difference which he notes is that the latter is mediated by the 'monopolisation' of the natural condition that allows such higher productivity of labour. But this mediation plays no role other than the 'formal transmutation' of surplus profits into ground-rent, which in turn 'transfers' the surplus value at stake from the capitalist to the landowner (Marx 1991a, 783–84, 870, 889). Now, if according to Marx there is no difference of *content* between extra surplus value and differential ground-rent, his discussion of the substance that constitutes the latter can shed light on the former. In this regard, it might be worth bringing up Marx's oft-quoted passage in which he characterises differential ground-rent as a 'false social value' (799); which, as discussed in Chapter 9, means that the surplus value which constitutes this form of social wealth must be the product of labour of workers exploited in other spheres of social production. As some scholars in this controversy over the source of extra surplus value have already pointed out (Itoh 1988, 241ff.; Sekine 2020, 551, 659–60), this text can most certainly be read as evidence in favour of the 'value transfer' thesis.

Substance, source and form of extra surplus value

As we have seen, one can plausibly read Marx's presentation of the generation of an extra surplus value in Volume I of *Capital* as a kind of 'external reflection' which, *strictu sensu*, does not belong in the precise level of abstraction in which he locates the discussion. On these grounds, this section aims at providing a brief positive exposition of the unity of the determinations which underpin the substance, source and form of extra surplus value. In doing so, we shall also try to throw into relief the main contentious points with regard to the different arguments put forward in the debate reviewed in the previous sections. In order to elaborate our own argument, we shall rely on textual evidence from Marx, so that this section's contribution also aims at providing a consistent methodologically-minded reconstruction of the systematic unity of the determinations of extra surplus value unfolded over the three volumes of *Capital*.[5]

As argued at greater length in Chapters 1 and 2, the specificity of commodity production derives from the fact that the immanent social character of individual labours is not carried as a *conscious determination* by private producers. This means that the establishment of the general unity of social labour is realised in an indirect form, through the mediation of the exchange of the products of labours as commodities, i.e. as unities of use-value and *value*. Importantly, we have emphasised that insofar as it is an objectified expression of the immanent social character of individual private labours, this dual determination of the products of labour is constituted in production and is only manifested in the sphere of circulation.

By contrast, a great deal of the Marxist literature, especially in the case of proponents of the 'potentiated labour' thesis, tends to adopt a different view. Specifically, several authors argue that what counts as 'socially necessary labour time' is also (or even exclusively, according to some scholars) determined by that which society is willing to validate in exchange in the form of effective purchasing power or monetary demand for the total output of a determinate branch of production. The determination of the magnitude of value would still derive from socially necessary labour-time, albeit not that objectified in the production of commodities, but that which society allocates in the form of effective demand (see, in particular, Busch et al., 1971 in the context of the German world market debate). As already argued in the appendix to Chapter 2, this essentially *circulationist* perspective conflates the qualitative and quantitative *content* of value, which is determined by the amount of privately-undertaken socially necessary abstract labour objectified in the production of a commodity, with its necessary *form* of expression and realisation as price, established through the interaction of supply and demand on the market. Crucially for the main argument in this section, we have emphasised that the 'quantitative incongruity between price and magnitude of value' (Marx 1976, 196) proves to be the necessarily haphazard mode which resolves, with the mediation of intra- and inter-branch competition between commodity producers, the 'quantitative articulation of society's productive organism' (202). In brief, the establishment of the material unity of the social division of labour in capitalist society must involve 'value transfers' among commodity producers.

Now, the products of private labour are not exchanged simply as commodities but as products of capital. In this more developed concrete form, both the transformation of value into price and the competition that mediates it, prove to involve further determinations. On the one hand, the 'quantitative incongruity' between the *content* of the value-determinations and its concrete *form* of realisation as market price in circulation, which results from the disequilibrium between supply and demand in a branch of production, becomes mediated in turn by the qualitative and quantitative *transformation of values into prices of production*. The latter are the prices that represent the equalisation of the rate of valorisation of the multiplicity of individual capitals determined as aliquot parts of the total social capital, given the respective differences in their organic composition and turnover times (Marx 1991a, 254ff.). On the other hand, and as a result of the previous point, the competition between commodity producers with a view to obtaining a selling price which represents the magnitude of value (i.e. 'normal prices') takes on the further concrete form of a competitive struggle to sell at market prices which allow the appropriation of the general rate of profit (273ff.). More importantly, since at this stage capital's immanent necessity to revolutionise the productive forces of social labour in order to produce relative surplus value has already been unfolded, the systematic-dialectical presentation can now explicitly consider the general concrete form in which individual capitals engage in the competitive struggle, namely: the introduction of technical change with a view to cutting the cost price of commodities, which in turn allows them to appropriate a temporary surplus profit. This actual modality of the competition process, explicitly determined as the concrete form that mediates the formation of the general rate of profit, turns out to be the phenomenon whose treatment Marx (1976, 433) opted preliminarily to bring forward to chapter 12 of Volume I, 'for the understanding of the production of relative surplus value, and merely on the basis of the results already achieved'. So let us examine the matter more closely.

By virtue of its determination as a concrete form of the establishment of the general rate of profit, all surplus profit entails a quantitative difference between the magnitude of value and its expression as price; *a fortiori*, this means that it necessarily involves a 'transfer of value'. At the level of *Capital* Volume I, all the aspects of this phenomenon could not be brought to the fore. Thus, we have already noted that in his provisional discussion of this issue in chapter 12, Marx categorially approached surplus profits as 'extra surplus value'. Moreover, in his numerical illustration, the analysis abstracted from all complexity regarding the quantitative differences between prices and values and the flows of monetary social wealth which they mediate. However, once the dialectical exposition has unfolded the formation of the general rate of profit, hence the self-negating realisation of values in prices of production that constitute the 'centre of gravity around which price turns' (Marx 1991a, 279), it is possible to incorporate greater complexity in the analysis of 'value transfers'.

Still, before proceeding to sketch out the main additional elements that need to be incorporated in a more nuanced examination of the constitution of surplus profits, we first need to distinguish between two different levels of abstraction. On the one hand, there is the simplest determination of value transfers involved in the exchange of commodities at market prices that express prices of production which coincide with values. On the other, there is a more complex determination of this phenomenon derived from the further value transfers involved in the quantitative difference between prices of production and values. Insofar as the Marxist debate tended to gravitate towards the former, in what follows our discussion will be carried out in that simpler level of abstraction.

Let us start by considering the process which establishes the socially *normal* conditions of production which underpin the determination of the value of commodities, when account is taken of competition based on technical change. At this juncture, a first point that is usually overlooked in the literature must be thrown into relief. We are referring to the rigorous systematic specification of the *qualitative kind* of technical conditions that enter in the constitution of the norm that defines the 'socially necessary labour time for the production of commodities'. In effect, the existence of technical change does not only imply that capitals are subject to *quantitative differences* in the productivity of labour that they set into motion. In addition, it also leads to the emergence of a qualitative differentiation among individual capitals regarding their (in)ability to take an active part in the formation of the general rate of profit. As we shall see at greater length in Chapter 8, this process of differentiation polarises individual capitals into *normal* and *small* capitals. For the purpose of this chapter's discussion, suffice it to note that although the latter lag increasingly behind in the pace of the process of concentration of capital demanded by the competitive struggle, there are different concrete determinations which allow them to remain in production despite their insufficient scale and backward methods of production. However, this extended lifespan goes hand in hand with their exclusion from the process of formation of the general rate of profit, i.e. they are precluded from valorising as 'aliquot parts' of the total social capital at the average rate of profit. For this reason, their conditions of production do not count for the determination of the *norm* that determines the value of commodities (Iñigo Carrera 2017, 102–3). In other words, it is crucial to bear in mind that the constitution of socially necessary labour-time is not expressed in the simple average that includes *all* conditions of production existing in a determinate branch of the social division of labour, but *only* those set into motion by capitals of a *qualitatively normal kind*, which are precisely those that still possess the potentiality eventually to push the technological frontier forward. On the other hand, it should be evident that from the fact that all normal capitals are qualitatively determined as potential active vehicles for the development of the productive forces of social labour, it does not follow that their conditions of production will be *entirely homogeneous*. At any moment in time, the productivity of labour set into motion by the different individual normal capitals will certainly vary, hence the form of an average assumed by the constitution of socially necessary labour-time. However, this will be a matter of *quantitative* differences within the *quality* of the *norm*. Moreover, it goes without saying that those differences will not crystallise in a rigid or permanent stratification. On the contrary, by virtue of the 'anarchic' nature of the competition process over the appropriation of surplus profits, it will be subject to continuous instability and reconfiguration, as now this or that individual normal capital temporarily succeeds in the race to push the technological frontier forward.

Now, in terms of value as the specific reified social form of representation of the socially necessary labour-time objectified in commodities, these determinations are expressed in the formation of the 'market value', which results from the average of the different 'individual values' that correspond *only* to the respective conditions of production of *normal* capitals in that sphere of the social division of labour.[6] In our view, this is the way in which Marx deliberately (albeit rather implicitly) framed the exposition of this process in chapter 10 of Volume III of *Capital* (Marx 1991a, 278ff.).[7] Seen in this light, insofar as the constitution of the 'market value' is predicated on diverse yet 'normal' individual labour-times, the inability of certain capitals to realise the full 'individual value' of their commodities is exactly mirrored by the appropriation by others of extra value over and above that which corresponds to the 'individual value' of their own commodities (279–80, 284–85).[8]

Having clarified the determination of the 'normal conditions of production' which express socially necessary labour, let us turn to give a closer scrutiny to the precise source of the surplus profits appropriated by innovating capitals. As we have seen, the extent of the quantitative divergence between market prices and values always depends on the relationship between supply and demand, i.e. on the mode in which capitalist society resolves the distribution of the social product through the circulation of commodities. Hence, in order to analyse the transfers of value that follow from the introduction of a technical innovation in a sphere of production, it is necessary to examine the effect of the consequent increase in output on the balance between the supply and demand for the different commodities. In a nutshell, three possible scenarios of the impact of the resulting relationship between market prices and values on the source of surplus profits can be discerned.

Insofar as the literature on extra surplus value that we have already reviewed in this chapter offers very nuanced and ample numerical illustrations, here we shall briefly concentrate on the essential conceptual aspect of the determinations at play.

Let us start out with the following extremely simple example. Suppose that there are three normal individual capitals in a certain sphere of production and that each of them produces 10 commodities with a unitary market value of $10, so that the total output in the branch is 30 commodities and the total market value amounts to $300. In this initial stage supply equals demand, market price and value coincide and so do all individual values with the market value. Let us now suppose that one of these individual capitals incorporates a technical innovation that allows it to double the productivity of labour, so that the individual value of its commodities drops to $5. Under these new circumstances, the total market value of the branch remains $300, but the total physical output goes up from 30 to 40 units of the respective commodity. Consequently, the unitary market value decreases from $10 to $7.5 (expressed through the average between all normal conditions of production in the respective sphere, which by assumption includes the three individual capitals in this example). Which possible variations of the relationship between market price and value, with the consequent generation of surplus profits and flows of value transfers, can turn out from this situation?

In the first scenario, which is the more widely discussed in the literature, the expansion of output from 30 units to 40 and the drop of the market value to $7.5, does not modify the magnitude of solvent social demand, which remains equal to $300 (i.e. ‘price elasticity’ of demand is 0). Therefore, the unitary market price of the respective commodities will fall to $7.5, which is exactly the new level of the market value. At this market price, the innovating capital will pocket a surplus profit of $2.5 per commodity sold, which amounts to a total surplus profit of $50. Conversely, the remaining two non-innovating capitals will suffer a loss of $2.5 per commodity, adding up to a total of $25 in each case. Evidently, the $50 that constitute the innovating capital’s surplus profit have their source in the loss experienced by non-innovating capitals. Thus, in this first scenario, there is a redistribution of value *within* the sphere of production, precisely because there is no ‘quantitative incongruity’ between market price and market value.

In the second scenario, the expansion of output and drop of market value to $7.5 upon the incorporation of a technical innovation by one of the three capitals in the branch, leads to an increase of monetary demand to $320. As a consequence, the unitary market price will undergo a smaller fall than in the previous case, to only $8. The innovating capital will thereby obtain a larger surplus profit of $3 per commodity, which will amount to a total of $60, whilst the other two non-innovating capitals in the sphere will experience a loss of $2 per commodity to a total, respectively, of $20. Aggregate losses in the branch will amount to only $40, which fall short of the $60 appropriated as surplus profit by the innovating capital. And this necessarily means that there must be a mass of value whose original source lies in *other* spheres of production. Thus, this scenario involves the same process which is always entailed by a market price that stands above the magnitude of market value: an inflow of more value to the respective sphere than that which is given up in exchange. In other words, there is 'non-equivalent exchange', which allows the appropriation in circulation of commodities that contain more objectified social labour-time than the amount that has been expended in the respective sphere of production (nevertheless, from the point of view of the *unity* of social labour, all privately expended labour-time will have been recognised by society and so all products will be 'stomached' by social consumption).

Lastly, in a third scenario, let us suppose that the expansion of output and the fall of the market value to \$7.5, effective demand in that sphere of production decreases to \$280.[9] The market price will fall below the new market value, more specifically to \$7. The unitary surplus profit of the innovating capital will come down to just \$2 per commodity, thus making the aggregate surplus profit equal to \$40. In turn, non-innovating capitals will lose \$3 per commodity so that their aggregate loss will total \$60, which in fact *exceeds* the \$40 surplus profit appropriated by the early innovator. However, those extra \$20 will not vanish into thin air but will flow through the exchange process over to other spheres of the social division of labour. This is just what actually happens whenever the market price stands below the immanent magnitude of value, namely: the respective sphere of production has privately expended more labour-time (hence produced more value) than the amount of objectified labour-time contained in the commodities against which it exchanges its output.

At this juncture, two additional points are worth stressing. In the first place, to the extent that this very simple example has been framed as an exercise in 'comparative statics', it cannot reflect the dynamic character of the process of formation of market prices and the social value. It thereby overlooks that all individual capitals, precisely insofar as they are *normal*, are in fact continuously increasing the productivity of labour that they set into motion, thus mediating the immanent necessity of the total social capital to produce relative surplus value. Thus, a subsequent technical innovation is likely to take place even before market prices complete the adjustment to the new magnitude of the social value. This will lead to the further reconstitution of the 'norm' that underpins the formation of socially necessary labour-time, thus rendering anachronistic the previously established 'centre of gravity' that regulated the movement of market prices of commodities. The latter is now surpassed by an even newer magnitude of the social value, which, again, will be rendered obsolete before market prices adjust to it, in a constantly renewed dynamic process of technical change.

In the second place, note that in all three scenarios, so-called 'value transfers' do not literally involve a movement of social wealth from one capital to another. Rather, it entails a 'double' flow of value in and out of the sphere of production in which the technical innovation took place. In other words, 'value transfers' are necessarily mediated by the exchange of commodities that contain unequal quantities of objectified socially necessary abstract labour. In this sense, the term 'transfer' seems ill-equipped to capture this greater complexity of the movement of capitalist social wealth at play. It is remarkable in this regard that Marx does not usually use this term but tends to speak of 'distribution' when referring to these movements of surplus value.

Conclusion

This chapter offered a critical reconstruction and assessment of the Marxist debate over the substance, source and form of extra surplus value. We have also gathered and systematised the textual legacy on the subject left by Marx. On that basis, we provided an approach to the phenomenon of extra surplus value which, we firmly believe, is consistent with the general foundations of the Marxian critique of political economy.

In our view, the recurring controversy around the theme of extra surplus value in the most varied Marxist debates, suggests that the matter merits to be addressed as a problematic in its own right. This conclusion is further reinforced by the theoretical richness and complexity of the substantive and methodological arguments that have been put forward in the two main theses which have crystallised out of this debate. Indeed, our discussion has shown that what at first might appear as conceptually inconsequential and easily comprehensible 'minutiae', turned out to be part and parcel of an eminently complex economic phenomenon which synthesises a highly mediated 'unity of many determinations'. On the other hand, it is also remarkable that in the past few decades, the debate has gained novel impetus among Marxist scholars. As we have seen, this renewed prominence of the problematic has paralleled and reflected the recent evolution of the broader Marxist debate on value theory, which ultimately provides the more general foundations of the different perspectives on the more concrete determinations that underpin the generation and appropriation of extra surplus value. Thus, we have also seen that the new consensus that seems to be materialising out of this more recent phase of the debate has strong 'circulationist' leanings, which is the general approach to value as a social form that tends to offer grounds to the 'potentiated labour' thesis.

As far as textual evidence from Marx's economic works is concerned, our discussion of the fundamental passages from Volume I of *Capital* which originated the dispute suggested that they are far from unequivocal. However, we have also argued that a solid case could be made that what appears in that context as 'extra surplus value' actually constitutes what *strictu sensu* are 'surplus profits'. Consequently, its systematic-dialectical treatment belongs to much more concrete levels of abstraction, a task which Marx managed to undertake only in a rather elementary way in the manuscripts which Engels edited and published as Volume III.

On the grounds of this reading of Marx's treatment of the subject in *Capital*, and through a critical dialogue with the different arguments brandished in the Marxist debate, we have presented our own synthesis of the essential determinations at stake in the constitution of the phenomenon of extras surplus value. In a nutshell, we have argued the constitution of the *content* of the social objectivity of value takes place in the sphere of production, whilst its *form* corresponds to the sphere of exchange or circulation. On this basis, we made a case for the consideration of extra surplus value as a surplus profit. And this implies that it must be grasped as a mass of value originally produced by wage-labourers exploited by other individual capitals, but which is appropriated in circulation by the early innovator. In terms of the two theses that have crystallised in the Marxist debate, this means that the source of extra surplus value resides in so-called 'value transfers'.

In sum, this chapter has hopefully shown that the *substance* of extra surplus value from innovation lies, in all possible scenarios of 'price elasticity of demand', in the privately-performed socially necessary abstract labour expended by wage-workers exploited by non-innovating capitals. In turn, depending on the precise relationship between market price and the magnitude of value that emerges upon the incorporation of technical change and the consequent expansion of output, the specific *source* of this extraordinary mass of capitalist social wealth can be found in other individual capitals from either the same or other branches of the social division of labour. Finally, we have stressed that regardless of its specific source, the *content* of the determination of extra surplus value is always expressed in the mystified *phenomenal form* of surplus profits.

Notes

1 In the original German edition, Marx uses the expression 'potenzierte Arbeit' to refer to what Fowkes translates as 'intensified labour'. As Ehrbar (2010, 1839) perceptively notes, this is blatantly wrong. Thus, here we have followed this author's suggestion to use the term 'potentiated labour'. A similar conclusion is drawn in Reuten (2017, 11–12).

2 Note that in chapter 12 of Volume I Marx does not consider the intermediary stages of the social value but only the initial and finishing 'equilibrium' magnitudes. The magnitude of this unitary social or market value is usually taken in this literature to be determined as the simple average that results from the total socially necessary labour-time expended in the branch and the respective aggregate output.

3 Iñigo Carrera (2017, 198–99) offers a similar analysis of these texts. Krätke (1997, 102–3) provides additional textual evidence, albeit in the context of the debate over 'skilled labour'.

4 It must be noted that in the post-humous edition of Marx's manuscripts, Engels added the term 'extra surplus value' in this passage.

5 In the instances in which Marx's own presentation falls short of developing all the determinations at stake, we shall also draw on Iñigo Carrera's intervention in the Latin American strand of the debate that we cited earlier on (Iñigo Carrera 2017).

6 As argued in the appendix to Chapter 2, whereas the social value is the representation of the socially necessary labour-time required for the production of a certain type of commodity, i.e. the direct reified expression of the normal conditions of production, the market value is its mediated monetary manifestation in the circulation process.

7 It is noteworthy in this respect that at the very beginning of the chapter on 'The Equalization of the Rate of Profit through Competition', Marx remarks: 'It would change nothing if, for whatever reason, capitals in certain spheres of production were not subject to the process of equalization. The average profit would be calculated on the portion of the social capital that was involved in the equalization process' (1991a, 274).

8 As we shall examine more closely in Chapter 9 on the debates over the nature of ground-rent, the mediation of non-reproducible natural conditions that differentially affect the productive powers of labour, modifies this role of the market value (formed out of an average among the individual productivities of labour of each normal capital) in the allocation of surplus profits or losses within the respective sphere of production (Iñigo Carrera 2017, 103–4).

9 Within the reviewed literature, only Iñigo Carrera (2017, 95–96) considers this last scenario.

7 Cognitive commodities and the growing role of intellectual labour in value-production

Introduction

Since the 1960s, the production of relative surplus value has been driven by the development of the so-called microelectronics revolution and the consequent emergence and ever-wider diffusion of information and communication technologies. These transformations have involved a leap forward in the complexification of labour and the multiplication of its intellectual powers. In turn, as we have seen in Chapter 5, these mutations of the productive subjectivity of the working class have been constituted and reproduced through novel and greatly diversified ‘norms of consumption’. The diffusion of the internet in the 1990s, the subsequent spur to the digitalisation of information and, more recently, the appearance of artificial intelligence and other innovations which have further bolstered the automatisation of production, have further deepened this developmental tendency in the productive subjectivity of the collective worker. On the other hand, these transformations have been mediated by the reconfiguration of the so-called New International Division of Labour (Starosta 2016), which have dispersed the material unity of the more complex and simpler organs of collective labourer across national borders. As a result, some countries have tended to concentrate within their territories a higher incidence of increasingly complex and intellectual forms of labour-power which, from a narrowly-national perspective, has accentuated the image of a historical transformation of even vaster proportions. This has given rise to widespread ideological buzzwords such as ‘post-industrial society’, ‘information society’ or, more recently, ‘knowledge economy’, ‘cognitive capitalism’, etc. (Bell 1973; Castells 1996; Foray and Lundvall 1996; Powell and Snellman 2004; Touraine 1969).

Within Marxism, this notion of a radical break with classic ‘industrial capitalism’ has led many authors to call into question the validity of the ‘law of value’ in the current stage of capitalist development. More specifically, from the most diverse quarters many scholars have argued that in contemporary capitalism there is a growing hegemony of ‘cognitive’ commodities. These are commodities for which the knowledge objectified in their production predominates over the direct manufacturing labour required for the actual fabrication of its material support, which

DOI: 10.4324/9781003201939-8

acts as ‘carrier’ of that predominantly ‘ideal’ content constituting their use-value. Software or pharmaceutical articles are usually taken as emblematic in this regard. Thus, the argument goes, this specific material ‘ontology’ (Zukerfeld 2006) of these knowledge-intensive products of labour (involving their costless reproducibility, indivisibility, non-rivalry, non-excludability, etc.), allegedly clashes with the nature of value as ‘objectified social labour-time’. The value-form would, therefore, be forced upon use-values, through the ‘parasitical’ imposition of ‘artificial scarcity’ by means of juridical forms such as intellectual property rights.

Although not explicitly inferred in all strands of this literature, this train of thought does tend to suggest that we would be witnessing a profound essential change in the very nature of the capitalistic organisation of the social life process, which in turn would be leading to a ‘structural crisis’ of this mode of production, involving both the obsolescence of the ‘law of value’ and the immediate material possibility of a direct transition to communism. This is indeed the overt conclusion drawn by proponents of the ‘Cognitive Capitalism’ approach (Corsani et al. 2001; Moulier-Boutang 2007; Vercellone 2003; 2007). The latter is the latest theoretical development of the post-workerist current that emerged in the early 2000s as an attempt to systematise the previously advanced ‘immaterial labour’ thesis (Lazzarato and Negri 1991; Marazzi 1994; Virno 1990) into a coherent and unified research programme.[1] However, similar ideas on the idiosyncratic nature of knowledge-intensive commodities have been elaborated by various Marxist economists, albeit with the opposite conclusion concerning the alleged inability of the Marxian ‘law of value’ to account for the determinations of this kind of commodities and their current hegemony in social production (Fine et al. 2010; Foley 2013; Jeon 2010; 2011; Perelman 2003; Rigi 2014; Rotta and Teixeira 2018; Teixeira and Rotta 2012).

Against the backdrop of these diverse phenomena, whose broad *descriptive* empirical validity is beyond dispute, and the different literatures that try to capture them within a Marxist framework, this chapter critically examines the determinations of the content and form of value of so-called ‘cognitive’ or ‘knowledge-intensive’ commodities. First and foremost, we shall argue against theorists of ‘Cognitive Capitalism’ that claims about the crisis of the ‘measure of value in social labour-time’ rest on a rather crude understanding of the antithetical determinations of the commodity-form as the unity of use-value and value. Furthermore, we shall submit that recent alternative attempts by Marxist economists to respond to those controversial and challenging arguments also fail to go beyond the immediate appearances of this kind of commodity. In fact, whether they acknowledge it or not, in most cases these authors end up admitting very similar conclusions to the post-workerist thesis that we are living in an age of crisis of the ‘law of value’ as the dynamic principle presiding over the contradictory movement of contemporary capitalism. Finally, this chapter shows that a more rigorous approach to the critique of political economy can make sense of such commodities through the lenses of the qualitative and quantitative determinations of the value-form that Marx presented in *Capital*.

The ‘applicability’ of the law of value to knowledge-intensive commodities according to ‘Cognitive Capitalism’ theorists and Marxist economists

As already mentioned in the introduction, a central argument put forward in the literature on cognitive commodities is that they differ significantly from ‘physical’ ones due to the peculiar cost structure entailed by their knowledge intensity: there are extremely high costs of production involved in the first unit, whilst the costs of subsequent units are minimal and come down to the reproduction of the materiality of the support on which the previously deployed knowledge will be incorporated (Ordoñez et al. 2008, 43). The paradigmatic case, which is also the most widely discussed in the literature, perhaps is that of software, by virtue of the high intensity of the R&D intellectual labour which is required for its production and the rather insignificant weight of the direct labour needed for the incorporation of that knowledge-content into a material support and the subsequent replication of marketable ‘copies’.

On these premises, ‘Cognitive Capitalism’ theorists infer that this costless reproducibility of cognitive commodities makes the ‘law of value founded on the measure of abstract labor-time immediately dedicated to production enter into crisis’ (Vercellone 2007, 29). This sounds deceptively simple and intuitive. If the primacy of exchange-value over real wealth is predicated on scarcity (marginalism) or on the ‘difficulties of production’ (classical political economy and, in ‘Cognitive Capitalism’ approach, Marx as well), then it seems reasonable to conclude that the immanent determinations of the value-form cannot regulate the production of commodities for which ‘the time of labor directly dedicated to production becomes insignificant’ (33). Presumably relying on this apparent simplicity, ‘Cognitive Capitalism’ theorists hardly make any effort to actually flesh out and substantiate their arguments (Henninger 2007, 172). One could argue that, in the manner of vulgar economists, these scholars just ‘appeal to “commonsense”’ (Marx 1976a, 974) as the only reason for their rejection of the determination of the value of cognitive commodities by the socially necessary abstract labour expended in their production. However, we shall see that matters are much more complex, and the seemingly commonsensical train of reasoning is far from calling into question the subsumption of these commodities under the law of value.

By contrast, some Marxist economists have recently attempted to account for the peculiarity of knowledge-intensive commodities based on the law of value. Some contributions have argued that the labour that produces cognitive commodities is quite simply just another type of *unproductive labour*, whose capitalistic production is sustained through the appropriation of surplus value extracted in other branches of the social division of labour (Foley 2013; Perelman 2003). However, insofar as these use-values increasingly tend to represent an ever-greater share of the ‘immense collection of commodities’ in the form of which social wealth appears in the capitalist mode of production, this kind of argument tends to validate the thesis of ‘Cognitive Capitalism’ theorists on the ‘crisis of the law of value’ rather than responding to them.

Another group of scholars pointed out that the 'valueless' nature of knowledge-intensive commodities, which excludes them from subsumption to the law of value, is predicated on the general determination of value itself. In effect, the latter is not determined by the effective conditions in which commodities have been produced but by their socially necessary conditions of *reproduction* (Rigi 2014; Rotta and Teixeira 2018; Teixeira and Rotta 2012). Consequently, once the first unit has been produced, the subsequent articles must be sold at a value which corresponds to the labour which is necessary for the former's 'replication'. Thus, this approach concludes, these actually are *sui generis* commodities, since 'even though they have value as a qualitative determinant this value is quantitatively negligible' (Teixeira and Rotta 2012, 457). On the other hand, in order to account for the *price* of cognitive commodities, it is claimed that it is necessary to have recourse to the Marxian theory of *ground-rent*: these commodities would give rise to 'knowledge rents' which would be pocketed by 'knowledge lords' (Rotta and Teixeira 2018; Teixeira and Rotta 2012).

The first thing to note about this perspective is that, similarly to the previous one just mentioned, far from responding to the objections to the applicability of the law of value to cognitive commodities, it also reasserts them. More importantly, the main weakness of this train of thought is that no real case is made for the argument that value is determined by the conditions of reproduction other than the appeal to the authority of quotations from Marx which allegedly validates that stance (Rotta and Teixeira 2018, 383–85).[2] However, as Parkhurst (2019, 82) has sharply noted in his critique of Rigi (2014), those same passages could be read in a different sense: when Marx refers to the 'conditions of reproduction' he is not denoting those which correspond to the next batch of commodities which will be produced in some *possible* future state of affairs, but to the *actuality* of the 'social conditions existing at the time' (Marx 1976b, 318) in which commodities arrive on the market. Thus, Parkhurst correctly observes,

> By identifying reproduction, as opposed to production, as the real determinant of value, Marx is asserting that the labour time it most recently took to produce a batch of commodity units determines the amount of value contained in all commodity units of that type that are currently in stock, which may have been made at a lower level of productivity (with higher input costs and/or more labor).
>
> (Parkhurst 2019, 82)

As we shall elaborate in a subsequent section, a first corollary of this is that the privately-undertaken social labour contained in the 'first unit' produced does not cease to count as part of the socially necessary labour required to produce *the whole batch* of identical commodities which are currently taken to the market. Furthermore, it must be stressed that this determination of value by 'social conditions existing at the time' derives from the very specificity of commodity-producing labour, which is predicated on its character as private, autonomous, and mutually independent from the rest of the individual organs of social labour.

By virtue of this specific social form, the recognition of private labour's socially necessary character can only take place at the phase of exchange (and only represented in the form of the attribute of exchangeability of its product, i.e. in the objectified social form of value). But at that moment only the labour-time which is *currently and effectively* necessary for the material reproduction of society can be taken into consideration; not that which corresponds to *prospective* material conditions of production which do not presently exist as an actuality and which will be privately set into motion as part of a *future* cycle of human metabolism, and whose socially necessary character is yet to be determined (in production) and validated (through exchange).

In opposition to those works which aim at offering an explanation as to why knowledge-intensive commodities do not have value, other scholars have attempted to flesh out the precise sense in which the cognitive labour which is necessary to produce these use-values does become represented as part of their value. The most sophisticated approach perhaps is that by Fine et al. (2010), building on the original contributions by Jeon (2009, cited in Fine et al. 2010) to the Korean debate on the subject (see also, Jeon 2010; 2011; 2015). According to this approach, cognitive labour creates value insofar as it 'potentiates' the value-positing powers of the direct labour which produces knowledge-intensive commodities. It is considered as a similar mechanism to that which Marx (1976b, 435) discusses in relation to 'exceptionally productive labour' and '[m]ore complex labour' (135). More specifically, Jeon (2010, 107) refers to this multiplication of the value-producing powers of labour as a 'virtual intensification of commodity-producing labor', a 'social processes by which the same amount of labour time produces more value without any changes to the intensity of labour due to, for example, the use of better knowledge within a sector or across sectors'. Thus, Jeon's argument concludes, 'labour becomes more productive in the former, and more complex in the latter' (107). In sum, this perspective considers that the greater value of knowledge-intensive commodities derives from the fact that their direct labour process becomes 'potentiated' by the prior cognitive labour on which it is premised.

Now, there are various problems with this argument. As we have seen in Chapter 4, the multiplication of the value-producing powers of complex labour does not derive from the 'accumulation' of past labour performed by *other* individuals, but from the 'formative' simple labour previously undertaken by the respective labourers themselves to develop their *more complex* labour-power. Yet this is not what is at stake in the production process of knowledge-intensive commodities, where the labour-power exerted in the final phase which produces the finished article –in the case of software, marketable copies– is relatively *simple*. In addition, we have also seen in Chapter 6 that the 'potentiation' of labour of a greater productive power does not entail the production of more value per unit of time, but the appropriation in circulation of an extra surplus value whose source lies in that extracted by other individual capitals. As Marx puts it, labour of a higher productivity is not potentiated in its value-producing powers, but 'acts as' if it were so. Be that as it may, this angle on the question is incapable of shedding light on the *general* determination of the value of cognitive commodities, since at stake in the discussion of *extra* surplus value is not the constitution of the *norm* that establishes socially necessary labour-time, but of *temporary individual deviations from it*.

Lastly, also among those who seek to defend the 'applicability' of the law of value to knowledge-intensive commodities, some authors maintain that the cognitive labour undertaken to produce the first unit is apportioned to each element of the total mass of marketable commodities of that kind (Carchedi 2014; Fuchs 2009; 2017). As we shall show below, the general thrust of this approach is essentially correct. However, the idiosyncratic 'temporalist' perspective that informs these contributions renders them incapable of responding to the case for the 'valueless' nature of cognitive commodities based on the alleged determination of value by the conditions of reproduction.[3] Moreover, also on these 'temporalist' grounds, some scholars further claim, wrongly in our view, that '[t]he production time of the necessary knowledge is best assigned to the first turnover period of capital'. They thereby conclude, equally mistakenly, that 'the sale of knowledge at prices above its economic value is the central value-theoretic mechanism in the process of accumulating capital with knowledge products' (Fuchs 2009, 398).[4]

Material specificity and value of knowledge-intensive commodities

Despite the air of self-evidence, the alleged inapplicability of the law of value to knowledge-intensive commodities rests on a fundamental error about the immanent determinations of the value-form of the product of labour. More specifically, this line of reasoning stops short at the *appearance* presented by the determination of value when the commodity is considered abstractly, as the *premise* of capitalist production (Marx 1976a, 953ff.).

In effect, when analysing the individual commodity as such, each of them is considered by Marx (1976b, 129–30) 'an average sample of its kind'. This means that at this level of abstraction, the diversity of individual circumstances can be ignored, and that the organic relation between the determination of value of each singular commodity and that of the mass of which it is part can be momentarily left aside. The individual 'part' can be considered apart from its relationship with the broader 'whole', for the time being, and therefore each commodity is analysed at this stage in isolation, as an autonomous individual product. The *relation* of the individual product with the mass of which it is part does exist but, as it were, only extrinsically, through the determination of the individual commodity as an 'average representative'. This also implies that the divergence between the labour expended in any single commodity and any other is, at this stage, immaterial. And this obviously includes the relation between the 'first' cognitive article produced and the reproduction of subsequent identical items of its kind.[5]

But matters are very different when the commodity is no longer considered as an abstract form of capital or as its premise, but as its immediate product or result. This is the subject of Marx's investigation in the *Results of the Immediate Process of Production*, where he shows that the re-examination of the commodity as the product of capitalist production brings new light to the value-determinations. In fact, it is mainly in that text that we can find Marx's most explicit and extended discussion of the central question that concerns us here in order to solve the 'riddle' of the cognitive commodities that puzzles post-workerist authors and Marxist economists alike: the inner nature of the individual commodity as a component part of a form-determined total product of the process of capitalist production (Murray 2009, 165).[6]

Marx (1976a, 953–54) states right at the outset of those manuscripts that, as the product of capital, the commodity emerges differently from the commodity taken as a single product, with which the dialectical exposition began. In this more concrete context, the commodity 'changes in form' (969), it becomes a 'depository of capital that has valorized itself' (965) and must, therefore, be considered 'as the *product of a total capital*' (971) that embodies a part of the total surplus value generated by it. As a consequence, the determination of the value of the individual commodity can no longer be considered in isolation but must be directly posited in its organic relation to the mass of commodities whose unity embodies the valorisation of the capital invested. As Murray (2009, 164) perceptively notes, Marx's (1976a, 949) shift from singular to plural in his first contrasting reference to the commodity as premise and product of capital is far from arbitrary.

In effect, as 'the transfiguration of capital that has valorised itself' (Marx 1976a, 954), the individual commodity does not simply appear as an autonomous thing that possesses value inasmuch as it is the result of a determinate quantity of privately-undertaken socially necessary labour (969). Instead, it becomes further determined as the material bearer of the value of the capital advanced (the part of constant capital transferred during the current production process, plus the variable component reproduced by living labour), together with the surplus value resulting from the exploitation of the (collective) worker. However, each commodity contains only a fraction of the total surplus value generated by the movement of capital. The latter's *full* valorisation thus necessarily entails that the commodity be present and sold 'on the *scale* and in the *quantities* necessary to realize the old capital value and the old surplus value it has created' (954). The immanent result of the process does no longer consist in 'individual goods', but a determinate 'mass of commodities' that acts as a depository of valorised capital and which must, therefore, be considered as a *single* (composite) commodity, i.e. 'as a single use-value […] whose exchange-value therefore also appears in the *total price* as the expression of the total value of this total product' (956).

In this more concrete mode of existence, the value of each single article is determined 'by expressing its use-value as an aliquot part of the aggregate product, and its price as the corresponding aliquot part of the total value generated by the capital invested' (Marx 1976a, 957). So, the individual commodity undergoes a transformation from an *average sample of its kind* into an *aliquot part* of the *total product of capital*. It becomes not just materially but *formally* determined as a singular element of the total mass of commodities produced by each individual capital. The relation between the 'the parts and the whole' suffers an inversion *vis-à-vis* the abstract appearance with which the exposition started. The value of the aggregate product no longer represents the simple addition of its constituent elements. Instead, the total value is determined 'first' and then shared out equally by each individual commodity, which now contains a proportional fraction of the former. At stake here is no longer an extrinsically connected aggregate of 'autonomous' individual commodities, but a mass of use-values which is given formal unity and consistency as a single total product that embodies the value of capital plus, above all, the surplus value to be realised (Marx 1989, 301).

In sum, we can now appreciate that the real determination of value actually transcends the isolated single commodity as such. The implications of this for the analysis of cognitive commodities follow quite straightforwardly. Seen in this light, the disproportion between the enormous 'cost of production' of the first original product and the costless reproduction of subsequent 'copies' loses the fantastic aura that captivates theorists of 'Cognitive Capitalism' and Marxist economists. There is no need to declare the obsolescence of the 'law of value' as the former would have it, nor to adapt it to a novel reality of costless reproducibility as the latter think. In other words, inasmuch as each single commodity embodies an equal fraction of the value of the product of capital as a whole, the comparison between the (exceptionally high) cost of production of the first article and (exceptionally low) cost of reproduction of the rest is rendered meaningless as far as their value-determinations are concerned. The alleged contradiction between this aspect of the specific material 'ontology' of cognitive commodities and the value-form is thus revealed to be a false one. This peculiar aspect of the materiality of cognitive commodities leaves the qualitative and quantitative determinations of the value-form intact.

Cognitive means of production and the formation of value

So far, we followed Marx's method of presentation of the simpler determinations of the value-form by treating the total socially necessary labour for the production of a certain commodity as an undifferentiated quantity that evidently included, but did not explicitly distinguish between, past and present labour. Although we did refer in passing to constant capital when discussing the commodity as a product of capital, we also tacitly followed Marx's presentation in that section of the *Results* in assuming that its value 'was entirely contained in and had entered into the product of the total capital under consideration' (Marx 1976a, 958). We must now drop that assumption and address the case of means of production whose value is transferred piece by piece to the finished product. This will allow us to expand our initial examination of the impact of the 'replicable material ontology' of cognitive commodities in the determination of the magnitude of value by socially necessary labour-time. Specifically, it will bring out additional elements that will show that the commodity must necessarily be thought of as part of a total product, and that therefore the contrast between the value of the first article and that of subsequent identical products is ill-conceived. We shall focus again on the case of software which, by virtue of the high intensity of the digital content of its use-value and the insignificant burden of the material support, is most expressive of the material constitution of cognitive commodities.

Let us first examine the simpler case of specialist programming software used for the development of a new application. Here there seems to be no essential difference with, say, a machine. From the point of view of the production of the new application, the specialised software is the material product of previous labour, which will be productively consumed in the current labour process, by appropriating its use-value to produce a new use-value. Assuming that the specialist software was bought from another private producer as a commodity, it will be a bearer of value. However, its contribution to the production of a different use-value means that the social usefulness of the labour materialised in it needs to be re-validated in the new material shape. Its value will be therefore transferred in the same magnitude to the finished product as the result of the activity of living labour in its concrete character. The functional role of programming software in the labour process becomes form-determined by positing that product of past cognitive labour as *constant capital*. And also as happens with a machine, the useful properties of specialised software as a means of production are realised over the course of more than one period of production, which means that its value will be transferred to the product fractionally, at a rate determined by the average useful life during which it acts as an objective factor of the labour process. It seems, then, that the 'weightlessness' of this peculiar cognitive means of production brings no essential modification to the process of value-formation.

There is, however, a rather significant difference. Unlike the case of a machine, software can be said to approximate a condition of material non-perishability (Zukerfeld 2006). The material support of this cognitive means of production might wear and tear as a result of the appropriation of its material properties, but not the 'knowledge-content', which can be preserved indefinitely as long as it is given an alternative physical carrier with minimal cost. This is one of the phenomena characterising knowledge-intensive commodities which some scholars throw into relief to make their case for the peculiarity of their production as material bearer of the value-creation process (Jeon 2011, 195). But what these authors tend to overlook is that besides material deterioration, means of production also experience *moral depreciation* (Marx 1976b, 528). In this sense, it could be argued that one of the most remarkable characteristics of software as a means of production is that the rate at which it will transfer its value to the final product *will almost exclusively be determined by its moral depreciation* (more on this below). Still, beyond this particularity, the functioning of this kind of cognitive product as means of production resembles that of machines.

With these form-determinations of software as a means of production in mind, let us now reconsider the problem of the apparent stark contrast between the value of the 'first unit' of a cognitive commodity and the 'valueless' nature of subsequent copies. For, strictly speaking, the 'first unit' of software actually is the 'prototype', the original digital file that contains the new application that has been developed and which will be used to make subsequent marketable copies.[7] The former is the use-value that is the immediate result of the mostly cognitive socially necessary labour of conception, design, etc. (briefly put, R&D). As Mandel (1976, 255) already noted in the early 1970s, the labour of R&D workers is an unambiguous part of the productive labour of the collective labourer, both of use-values and of value. But its direct result is not the finished product that eventually takes the commodity-form and is brought to the market. The production of the subsequent marketable copies –whether on a ‘physical’ carrier or by the ‘virtual’ transmission of a copy of the file through the internet–, entails the production of a use-value which is materially different from the original file, and it is in this very final objectified shape that the overall labour required from its production must still manifest whether it was expended in a socially-useful form or not. From the perspective of the production of the finished product, the ‘prototype’ represents past objectified labour. It must, therefore, not be treated as part of the actual *result* of the process of production of software. From the perspective of the final phase of the collective labour process that produces software as a commodity, the socially necessary labour of R&D that results in the prototype produces a *means of production* and, more concretely, an *instrument of labour* –whilst the raw material comprises the electric pulses which will be given the material form needed for their ‘virtual’ transmission and reception through the internet. Like the case of the making of earthenware melting pots by glass manufacturers reported by Marx (1976b, 465) in *Capital*, the production of the ‘means of production is here united with that of the product’. It is the product of the separate labour process of a special organ of the collective labourer as a whole, whose *common final product*, made up of the subsequent mass of marketable copies, becomes a commodity (475).

These further determinations of the process of value-formation for cognitive commodities such as software allow us to concretise the quantitative determination of the volume of the mass of commodities that must be considered as the materialisation of the socially necessary labour for its production. Once we make the distinction between past and present labour explicit, this mass of commodities acquires an immanent *diachronic* dimension: the software ‘prototype’ maintains its role in the formation of value as long as it remains socially-useful, i.e. indirectly satisfies a social need by acting as a means of production of additional copies. Given its specific ‘non-perishable’ character, the social usefulness of the software prototype has the peculiarity of being subject to virtually no material limit springing from its physical deterioration. Unlike the case of ‘hardware’, the relevant volume of commodities is almost purely determined by the ‘moral’ useful life of the software prototype. The latter is given by the existence of a social need for the finished marketable product (the ‘copies’), which in turn usually depends on whether those products have been displaced by similar ones (Marx 1976b, 201).

Against the backdrop of these determinations, it makes no sense to consider, as much of the literature that we reviewed does (Foley 2013; Perelman 2003; Teixeira and Rotta 2012), that the cognitive labour objectified in the ‘prototype’ is unproductive. R&D labour necessary for software is, above all, productive of use-values insofar as it produces a means of production. More importantly, since it is undertaken in a private and independent manner, it is value-producing. Lastly, to the extent that is performed under the command of an individual capital, it is productive of surplus value.

The confusion over the functional determination of the first unit in the process of production is particularly manifest in the case of Rotta and Texeira (2018, 386), who stress that it is 'crucial to distinguish between the knowledge-commodity itself and other tangible and non-tangible commodities that it might be attached to'. On these premises, they conclude that a knowledge-intensive commodity entails 'in fact a combination of more than one commodity': the 'knowledge-commodity' and 'technical artifact in which information is stored' (387). Now, not only is the knowledge objectified in the first unit not a commodity but, above all, it neither is a means of production. Knowledge or cognition is an inner moment of human productive action, an attribute of labour-power which is expended as labour whenever it is set into motion. In this sense, it can only exist outside the corporeality of the labourer in the form of objectified knowledge, i.e. in a use-value. Thus, we have already seen that the first unit or prototype is not a commodity but a means of production in a labour process which will have as its product a whole batch of commodities whose value will be determined by both the direct living labour involved in the 'replication' of the prototype and all the past labour which was necessary to produce the latter, including that expended in the R&D process. On the other hand, even if R&D labour were independently performed in a formally autonomous private fragment of the social division of labour, knowledge itself would not be the marketed commodity: it could only become so once objectified in a separate product, which would eventually be bought as means of production by another individual capital.

At this juncture, it transpires that the argument about 'costless reproducibility' is premised on the inability to establish with clarity and precision the starting point and endpoint of the labour process of knowledge-intensive commodities. More specifically, this train of thought abstractly tears asunder the material unity between past objectified social labour and current living labour. Rotta and Texeira (2018) have sought to elaborate on this argument based on textual evidence from Marx in which he allegedly would be postulating that value is determined by the conditions of reproduction of commodities, idiosyncratically interpreted as signifying the amount of labour-time which is necessary to produce anew each subsequent unit of a commodity. In this manner, they infer that the first unit of a determinate kind of commodity, which according to them exclusively condenses the whole amount of R&D labour expended, suffers an instantaneous process of total moral depreciation in the face of the virtually costless replication of new batches of the same commodity (Rotta and Teixeira 2018, 384–86; 391–92; see also Rigi 2014, 911–12).

Yet, we have already pointed out that the passages from Marx which these scholars bring up as textual evidence can more sensibly be read as entailing that the conditions of reproduction are those which in *Capital* Volume I Marx refers to as the 'social conditions existing at the time' (Marx 1976b, 318), i.e. those which are necessary to produce a certain type of commodity at the very moment in which they arrive at the market, which certainly might differ *both* from the *past* conditions which were effectively required by 'all the old commodities of the same type' (318) that are still in stock and *also* from those future conditions which might be socially necessary in the *future*. As a matter of fact, against the backdrop of our prior discussion of the functional connection between past objectified social labour and the current expenditure of living labour, it is remarkable that these authors choose not to thematise this piece of textual evidence, which is located precisely in the systematic context in which Marx explicitly considers the manner in which the socially necessary labour-time objectified in means of production reappears as part of the value of the final product.[8] Thus, if the first unit is considered as a means of production, it follows rather straightforwardly that all the socially necessary labour-time expended in its production (and that clearly includes R&D labour) forms part of that which is necessary to produce that particular kind of knowledge-intensive commodity. There is nothing peculiar about this; it is what happens with any means of production utilised in that labour process. On the other hand, the idea that the first unit experiences instantaneous moral depreciation does not only fail to comprehend the meaning of the determination of value by 'the social conditions existing at the time' but also fails correctly to grasp the actual process involved in the phenomenon of moral depreciation itself. The latter only occurs whenever the *same* means of production are re-utilised in a subsequent labour process for a certain type of commodity, but in *changed* social circumstances, e.g. *other* means of production 'of the same sort are produced more cheaply' or better *substitutes* 'are entering in competition with it' (528). By contrast, in Rotta and Teixeira's idiosyncratic understanding, moral depreciation obtains by an alleged economy in a subsequent utilisation of *living* labour by the same individual capital. In sum, although it is correct that to the extent that cognitive means of production are bought as constant capital, they suffer almost exclusively from moral depreciation only, the reason for this is that they do not experience practically any material wear and tear, and not because the same individual capital can materially economise on their use once the first unit of the final product is produced.

Finally, this reconsideration of the relationship between all past objectified labour and current living labour which are socially necessary to produce cognitive commodities shows that, *pace* Fine, Jeon and Gimm (2010; Jeon 2010; 2011), there is no process of potentiation or virtualisation between them. As we have seen, from the standpoint of the valorisation process, the R&D labour objectified in the prototype does not differ from that applied to the making of earthenware melting pots in glass production, which Marx mentions as an example of the manufacturing manual division of labour: it is part of the total socially necessary labour under the command of an individual capital, whose sole distinguishing feature is that it becomes objectified in what is functionally determined as a means of production of the labour process whose final product is a whole batch of cognitive commodities.

The economic content and juridical form of cognitive commodities

Does the previous discussion imply that the phenomenon of 'costless reproducibility' of cognitive commodities is entirely irrelevant for the understanding of contemporary capitalism? Actually not. Although this characteristic does not transform the normal 'laws' that regulate the *production* of *value* of commodities, this material specificity does impinge on the conditions of *appropriation* of their *use-value* and, therefore, on the *realisation* of their *value*. The contemporary prominence of discussions around *intellectual property rights* essentially derives from this peculiarity of cognitive commodities.

In effect, what *is* distinctive about cognitive commodities, derived from their so-called costless reproducibility, is that their use-value can be appropriated as a *means of production* of further identical use-values (e.g. subsequent copies of the original software) without virtually any cost. Unlike 'physical' commodities, almost no new living labour or additional costly means of production are involved in, say, copying a digital file containing software. As we have seen, this does not alter the determinations of the *production* of value. But it most certainly does affect its *full realisation* and therefore gives a specific character to the juridical form that necessarily *mediates* it. The latter must not simply codify the possession of commodities as legal ownership, but also needs to regulate the conditions of appropriation of their use-value by, for instance, prohibiting home-copying or sharing of proprietary software, and more generally, its reproduction, modification improvement and redistribution, especially for commercial purposes (this is usually accompanied by *technical* barriers to the appropriation of its material properties through non-accessible source codes). This is necessary to prevent the appearance of competitors that can produce identical commodities without the need to incur all the costs involved in software development (Husson 2004). In brief, in preventing potential situations like this, intellectual property rights do not force the exchange-value of software above its insignificantly small (or inexistent) value, as claimed by theorists of 'Cognitive Capitalism' (cf. Rullani 2000), and also by Marxist economists who resort to the theory of ground-rent to explain the exchange-value of knowledge-intensive commodities (Perelman 2003; Rigi 2014; Rotta and Teixeira 2018; Teixeira and Rotta 2012; Zeller 2008). On the contrary, intellectual property rights are the necessary mediating juridical form for the full realisation of their value. This simplest juridical form assumed by the realisation of the value of cognitive commodities is already present in their more abstract mode of existence as premises of capital. But it is obviously further developed in their actual determination as products of capital, in which case intellectual property rights essentially become juridical forms taken by the realisation of surplus value.

The crucial point to highlight is that the juridical form does not 'artificially *impose'* the (materialised) economic relation (the value-form). Instead, intellectual property rights, however necessary, only *mediate* the realisation of the economic content, whose foundation still rests on the specific *social form* taken by the organisation of the human metabolic process in capitalism, i.e. the private and independent form of the production process of use-values. The 'peculiar ontology' of cognitive use-values does not compromise these simpler determinations of property rights that Marx (1976b, 178–79) unfolds at the beginning of his presentation of the exchange process in chapter 2 of *Capital*. In this sense, there is no essential difference between cognitive commodities and 'physical' ones beyond the technicality of extending the legal regulation beyond the act of exchange proper and into the conditions of use. The juridical form of the contract must consequently assume a more complex form. But there is nothing conceptually out of the ordinary in it which would be signalling that we are witnessing capital's desperate attempts to subsume a production of use-values whose immanent logic 'ontologically' escapes the latter's form-determinations, or a novel form of rent appropriated by the new figure of the 'knowledge lord'.

Having declared that cognitive commodities have no immanent 'economic value' as a consequence of their costless reproducibility, a great deal of the literature under discussion also adds that, resembling so-called public goods, they are 'non-rival' and 'non-excludable' (Moulier-Boutang 2007, 163; Perelman 2003, 305; Teixeira and Rotta 2012, 462; Rotta and Teixeira 2018, 389).[9] In the specific case of the theorists of 'Cognitive Capitalism', they thereby conceive of this determination as undermining the two foundations on which exchange-value (economic content) and private property (juridical form) respectively rested: scarcity and rivalry/excludability (Moulier-Boutang 2001, 24–25; Vercellone 2007, 34). Thus, from this viewpoint, these goods can only be turned into commodities and be subject to private appropriation 'artificially', through the social creation of scarcity by means of 'anachronistic' property relations. Inasmuch as the immanent value-determinations no longer operate in the case of cognitive goods, the juridical form must secure the parasitic imposition of a 'fictitious' economic content (exchange-value), reduced to nothing but an 'empty husk' (Vercellone 2008).

The main problem with this line of reasoning is that despite its anti-capitalist sentiment and rhetoric, it remains firmly trapped within the bourgeois horizon of mainstream economics. For even when it aims to provide weapons for the struggle against the commodity-form, it too uncritically borrows the conceptual foundations of its practical critique from the neo-classical theory of the market and property rights and simply gives them a 'radical twist'. Indeed, the validity of neo-classical arguments for the 'necessity' of the value-form (scarcity) and for the legal regulation of the private appropriation of use-values (rivalry, excludability) is implicitly accepted for ordinary commodities and the era of 'industrial capitalism'. The problem seems to reside not so much in those marginalist arguments themselves, but in their scope of applicability when an increasingly greater part of social wealth consists of knowledge-intensive commodities, as happens in the age of 'Cognitive Capitalism' (Moulier-Boutang 2001, 24ff.). Whereas ordinary private property is tacitly accepted as an *absolute* necessity for the stage of humanity's history of 'struggle against scarcity' in which 'material' commodities were hegemonic (Vercellone 2008), intellectual private property has become a historical aberration that blocks the further development of the productive forces.

But the point is that the specific material properties of commodities did not ever constitute the foundation of the value-form and private property, not even during what 'Cognitive Capitalism' theorists (wrongly) see as the now defunct age of industrial capitalism. The products of labour were never commodified because they were 'naturally' scarce; their exchange-value was never simply determined by the 'difficulty of production' (i.e. the human overcoming of natural scarcity); and their private appropriation was never founded on their 'rivalry and excludability'. This fetishistic form and its juridical expression do not derive from the material characteristics of the product but from the specific *social form* in which its production process is organised (Nuss 2005). The products of labour take on the value-form because they have been produced in the form of private and independent labour. The critique of the commodity-form of cognitive goods based on the moral denunciation of 'artificial scarcity' leaves the attribution of the form of general exchangeability of 'physical' commodities to 'natural' scarcity untouched. In the end, it uncritically falls prey to the fetishism of the commodity-form of the product of social labour.

For their part, Marxist economists attempt to salvage Marx's 'law of value' in the face of the peculiar 'ontology' of knowledge-intensive commodities through an extrapolation of the theory of ground-rent. They thus argue that when a 'naturally' non-scarce use-value is transformed into a commodity by virtue of the artificial scarcity imposed by intellectual property rights, 'monopoly rents' arise. Moreover, they also maintain that when the use of commodified information leads to the multiplication of the productivity of labour, 'differential rents' emerge (Rigi 2014; Rotta and Teixeira 2018; Teixeira and Rotta 2012). As happens according to Marx's own explanation of ground-rent, some scholars further acknowledge that intellectual private property allows the capture of surplus value extracted in other branches of social production (Foley 2013). In a nutshell, these scholars try to capture these related phenomena with reference to the category of 'information rents' and 'tribute rents' (Rigi 2014), or 'knowledge rents' and 'knowledge lords' (Rotta and Teixeira 2018). Yet, as these scholars themselves recognise, there is an essential difference with respect to ground-rent: whilst at stake in the latter are natural conditions which are non-reproducible by capital, access to the 'knowledge-base' which underpins 'cognitive commodities' is artificially made scarce through the state-mediated monopoly power of capitals which produce those commodities. This is the reason why Rigi eventually admits that his argument is heir to the classic theory of 'Monopoly Capital' pioneered by Hilferding and Lenin (Rigi 2014, 916).[10]

Regardless of other problematic aspects of this latter explanation, the main issue with it is that rather than salvaging Marx's 'law of value' for the era of 'Cognitive Capitalism', it ends up undermining it as well. Although these scholars do not necessarily agree with the theorists of 'Cognitive Capitalism' on the 'value-less' content of knowledge-intensive commodities, they nonetheless ground their exchange-value in the 'power' of capitalists to impose their will on the market. Thus conceived, as Hilferding (1981, 228) claimed in the original version of the theory of 'Monopoly Capital', 'price ceases to be an objectively determined magnitude and becomes […] subjective rather than objective, something arbitrary and accidental rather than a necessity which is independent of the will and consciousness of the parties concerned'. Consequently, instead of grasping capitalism as an alienated form of the social life process through an objectified form of social mediation turned into an automatic subject, this perspective depicts it as organised under the rule of the consciousness and will of certain individuals. Put differently, this modern version of the old 'Monopoly Capital' theory also forgets that the subject of the accumulation process is the total social capital and not particular individual capitals (Iñigo Carrera 2013, 163ff.). If intellectual property rights were allowing the systematic appropriation of monopoly rents in strategic sectors by permanently sustaining market prices above prices of production, the production of relative surplus value itself would be hindered. The total social capital would sooner or later intervene directly (i.e. through the state) to discipline those rebellious individual capitals and remind them that their apparently autonomous actions are nothing but the immediate personifications of the former's necessity to reduce the value of labour-power in order to extend the part of the working day that corresponds to surplus labour.

Finally, the above discussion of R&D labour allows us to enrich the economic content of intellectual property rights. The increasingly systematic and intensive link between knowledge and social production does not have its immediate purpose in the development of human powers as an end in itself, but in the production of a surplus profit from innovation for the individual capitalist (Mandel 1976, 253). In turn, the latter is the necessary concrete form in which relative surplus value is produced by capital as a whole. In protecting the valorisation of R&D capital from risks of appropriation of its products as means of production by competitors, intellectual property rights, therefore, mediate not only the full realisation of value and surplus value but, more concretely, the appropriation of an extra surplus value by successful innovators. They, therefore, reproduce the conditions needed for the production of relative surplus value by the total social capital through the actions of its formally autonomous individual fragments. But they can only do so for being only *temporary* surplus profits that realise the *equalisation* of the rate of profit of *normal* capitals at that general level in the form of its opposite, namely, through their constant inequality. In other words, besides exceptional particular circumstances, intellectual property rights are a mediating juridical form in the formation of the general rate of profit and not, as much of the literature usually assumes, a barrier that 'artificially' creates the conditions of extraction of *monopoly* rents, whether because by definition the price of these commodities would otherwise tend to zero or, in more nuanced approaches, because 'similar to a land estate, a patent-based property monopoly inhibits any additional capital from flowing into the sector enclosed by the property title. For this reason, the surplus value produced within this "protected" area cannot flow into general equalization' (Zeller 2008, 99).

But precisely the very fact that captures the attention of these scholars, namely the generalisation of intellectual property rights and the expansion of their scope of application, seems to suggest that they are becoming the *normal* condition for the valorisation of capital as the 'cognitive' content of commodities increases. Unlike land, which is a natural condition *not reproducible* through human labour, objectified knowledge is the product of intellectual labour. Nothing would prevent other capitals from generating in time their own 'patentable knowledge' which, even if different from the very singularity of the knowledge of the first-mover, would still be capable of being mobilised to produce substitute use-values in equivalently productive conditions that would sooner or later erode the surplus profits of the original innovator. This, in turn, suggests that intellectual property rights are the juridical form taken by the tendential *equalisation* of the rate of profit of *normal* capitals, that is, of those that reach the *specific magnitude* '[that] is required in each line of business to produce commodities at their price of production' (Marx 1991, 843) and which nowadays must include heavy investment in R&D.[11]

Conclusion

In this chapter, we have sought to offer an alternative response to the challenges posed by 'Cognitive Capitalism' theorists and Marxist economists to the nexus between the Marxian law of value and the phenomenon of cognitive or knowledge-intensive commodities. The former quite simply declares the obsolescence of the law of value in the face of the alleged costless reproducibility of this kind of commodity. By contrast, Marxist economists are at pains to make a case for the continued contemporary validity of the law of value, by specifying the peculiar mode in which it would regulate the production and exchange of these commodities. Yet, most of these contributions end up accepting that knowledge-intensive commodities do not possess any (magnitude of) immanent value. Their price is thus said to be established through the imposition of artificial scarcity sustained in the monopoly power of those capitals that produce them. On the other hand, in the cases of contributions that still conclude that cognitive commodities have value, they do so on deficient or insufficient grounds.

In a nutshell, our main alternative argument was that knowledge-intensive commodities are no different from 'ordinary' ones with respect to their mode of subsumption to the law of value. In other words, the form-determinations of the commodity that Marx unfolded in *Capital* fully operate in the case of these products of labour despite their undeniable material peculiar features. More specifically, the following are the salient points that we attempted to make. First, we showed that the value of each singular commodity is given by its condition as an individual element or aliquot part of the total mass of the same type of commodity that results of the process of self-valorisation of the respective individual capital. Consequently, the clearcut distinction between the first and the successive units of the same article which is key in the Marxist controversies on cognitive commodities is actually not of the essence for the comprehension of this phenomenon. Second, we demonstrated that the functional material determination of first unit produced, which is the immediate material objectification of the R&D which is necessary to produce knowledge-intensive commodities, is to be a means of production for the subsequent labour process which replicates this 'prototype'. If the latter is produced in a formally separate private and independent fragment of the total social labour (i.e. under the command of a different individual capital), it will be form-determined as constant capital for those downstream individual capitals that buy it as a commodity and utilise it in their respective valorisation process. If the production of the first unit is undertaken under the command of the same individual capital which produces the marketable 'copies', R&D labour will nonetheless still be part of the total socially necessary labour to produce the whole mass of the latter and will be proportionally represented as value across each individual element.

Thus, the alleged 'costless reproducibility' of cognitive commodities turns out to rest on the forced abstraction of past, objectified labour from the total socially necessary labour to produce them. Finally, we argued that intellectual property rights which regulate the appropriation of the use-value of cognitive commodities are not the way in which monopoly capital imposes artificial scarcity but juridical forms which mediate the full realisation of their immanent value.

Notes

1 The 'immaterial labour' thesis is also a central element of *Empire* (Hardt and Negri 2000) and *Multitude* (Hardt and Negri 2004), two highly-influential books by leading post-workerist authors.

2 Among these pieces of evidence, Rotta and Teixeira (2018, 386) cite the following text from Marx's economic manuscripts from 1861 to 1863: 'The product of mental labor – science– always stands far below its value, because the labour time needed to reproduce it has no relation at all to the labour time required for its original production' (Marx 1994, 87). Leaving aside the unsystematic, in-passing character of this passage from an unpublished draft of the Marxian critique of political economy, it is noteworthy that Marx does not claim in those lines that the product of scientific labour is 'valueless' but, to the contrary, that it is sold 'below its value'. As we shall see later, one of the peculiarities of knowledge-intensive commodities is that in order for its price to correspond to its value, specific juridical forms must mediate their conditions of production and circulation. And these conditions were extremely underdeveloped in Marx's time.

3 The so-called 'Temporalist Single System Interpretation' of Marx's value theory is a current among Marxist economists which have emerged in debates around the transformation of values into prices of production (see Kliman and McGlone 1999). A key idea in this approach has been that the transfer of the value of constant capital to the final product must not be considered in terms of the 'pre-production *reproduction cost*' but on the basis of '*historical cost*' (Kliman, 2007, 96). As we shall see later, this perspective is incorrect.

4 We shall elaborate on these issues later.

5 Nevertheless, there are elements in Marx's exposition of the 'isolated' commodity that anticipate, without unfolding, the more organic determination of its individual value as part of a mass that we discuss below. This is implicit when he analyses changes in the productivity of labour and its impact on the individual value of each commodity. There it becomes clear that value is already at this stage the reified objectification of the total labour expended for the production of a mass of commodities in a whole period of work (later specified as a normal working day), and that each commodity represents an aliquot part of the total quantity of value produced. The contradictory movement between the quantity of wealth (use-value) and that of value rests, precisely, on this point (Marx 1976b, 136–37). This simple quantitative determination of value disproves the idea that the value of the 'first' commodity produced represents all past and current socially necessary labour required for its production, whilst the value of subsequent articles comes down to the quantity of new living labour that is necessary for the production of the material support and the mere reproduction or copy of the knowledge-content from the 'original' cognitive commodity. Still, Marx does not draw the implications of this for the appearance of the commodity as an 'autonomous' materialisation of a specific quantity of socially necessary labour-time. His dialectical presentation of the commodity, therefore, continues *as if* the determination of value pertained to each individual article in isolation, albeit taken as an average sample of its kind.

6 In addition to the in-passing comments mentioned in the previous footnote, the other place in *Capital* where Marx explicitly presents this aspect of the determination of the value-form is the chapter on the Concept of Relative Surplus Value (Marx 1976b, 433–34). In fact, in Volume III of *Capital*, he makes a self-reference to those pages of Volume I precisely in order to contrast this inner determination of value with the inverted form in which it appears in circulation (and hence in the fetishised consciousness of the individual capitalist), namely: that price is fixed for the individual commodity and that the price of the total product is determined by multiplication (Marx 1991, 338). But, unlike in the *Results*, that question is discussed rather succinctly and does not constitute the focal point of the presentation.

7 Strictly speaking, the stable and marketable version of software is usually referred to in the specialised literature as the 'Gold version', the prototype proper being an earlier version which might still contain errors or technical problems (Blondeau 2004, 44).

8 Incidentally, those are far from 'obscure' passages but have been widely discussed among Marxist economists in the literature surrounding the temporal dimension of the determination of value (cf. Kliman 2007, 97–99; Moseley 2000).

9 Their non-rivalry implies that the use-value of cognitive commodities can be shared without loss of the available quantity of that use-value. In other words, one person's consumption does not diminish the amount available to other people (Varian 2001). Strictly speaking, this is not really a feature of these commodities. The alleged non-rivalry is based on the assumption that the real use-value is the knowledge-content, which is seen as an ethereal entity floating in mid-air, with the material support as a 'mere' physical guise (Zukerfeld 2009). But the use-value of a commodity is given by all the material properties in their indissoluble unity, including both the knowledge-content and the 'physical bearer'. Thus, the use-value of software thus comprises the unity of the digital content and the material support, which means that the consumption of each copy *is* rivalrous.

10 Rotta and Texeira are also aware of the similarity of this train of reasoning to the arguments of 'Monopoly Capital' theory. Yet, they do not seem ready to accept this intellectual lineage for their own argument. Thus, they attempt to part company with 'Monopoly Capital' theory by stating that it is 'a new theoretical problem' opened by 'the growing importance of knowledge-commodities' and 'the growing importance of state laws to guarantee the reproduction of commodities highly dependent on the systematic application of knowledge' (Teixeira and Rotta 2012, 464). However, it should be noted that the fact that the object to which it is applied might have changed, does not necessarily prevent the theoretical explanation from remaining the same.

11 See Chapter 8 for a more detailed development of the determination of normal capitals and the regulation of their formally autonomous action through the formation of the average rate of profit.

8 A critical look at Global Value Chains Competition and globalisation in contemporary capitalism

The case of the automotive industry

Introduction

The Global Value Chains (GVCs) approach can be regarded as a general theory of international development, which aims to provide an understanding of the world market which does justice both to its underlying 'structural' unity and the varied patterns of national differentiation. This approach sees the configuration of global production networks of individual firms as fundamental drivers of the novelty of phenomena generally associated with the 'globalisation' of the capitalist economy, defined in terms of the emergence of a pattern of global dispersion with functional integration of economic activities (Dicken 2003, 12). The concept of 'value chain' brought to the fore an often-overlooked aspect of capitalist relations, i.e. the differentiation of individual capitals in terms of valorisation capacity and of power asymmetries. Moreover, it allowed the GVC approach to highlight the relevance of the changing dynamics of these relations between capitalist firms as a crucial aspect of the process of 'globalisation' of the capitalist economy. For instance, one of the main contributions of the studies informed by the GVC approach was to offer rich empirical descriptions of the interrelated processes of outsourcing and relocation of manufacturing, which in turn involved important transformations of the 'supply relations' of most lead capitalist firms.

However, as we argued elsewhere (Starosta 2010a), the GVC approach ultimately fails to root these novel phenomena in the general laws of motion of capital as a whole. Consequently, it cannot actually provide a firm explanation of the constitution and dynamics of its own object of inquiry. In this context, our aim in this chapter is to propose an alternative account of the social determinations underlying the genesis, structure and evolving configuration of these 'value chains' on the basis of the Marxian critique of political economy. We shall start in the first section of the chapter with a discussion of the determinations of the 'chain form' taken by the current forms of capitalist competition, setting aside its global dimension for later scrutiny. In this section, we offer an actual explanation (in contrast to the overly descriptive GVC approach) of the differentiation of individual capitals based on Marx's discussion of the formation of the general rate of profit.

Whilst keeping our focus on the organisational dimension of GVCs, in the second section we turn to a more concrete discussion of recent transformations

DOI: 10.4324/9781003201939-9

in their composition and governance structure resulting from two interrelated processes. The first is the tendency for, on the one side, a growing specialisation of lead firms[1] in innovation and product development and, on the other, an increasing outsourcing of manufacturing activities to suppliers. The second is the transition away from more hierarchical governance forms comprising a network of small suppliers under the tightly structured command of chain drivers, with the rise of highly concentrated 'global contractors' or 'mega suppliers', which has led to a partial shift of the power asymmetry between brand-name firms and their suppliers. Subsequently, in the third section, we finally deal with the spatial dimension of GVCs' recent transformations. More concretely, in this part of the chapter, we examine how the rise of global contractors and mega suppliers has given new impetus to the development of the international division of labour revolving around the fragmentation of the different qualities and disciplines of labour-power, through the well-known process of relocation of manufacturing to 'low cost' regions and countries. In both 'organisational' and 'spatial' aspects of GVCs dynamics, we argue that the Marxian critique of political economy can provide solid foundations for the comprehension of the aforementioned transformations.

Lastly, the fourth section offers an illustration of our perspective through the examination of the recent transformations of the global automotive industry. This will serve to show the concrete implications of the main points developed in the first three sections. Moreover, this brief sectoral study will provide a complementary case to our previous analysis of the electronics GVCs (Starosta 2010b), allowing us to evaluate the concrete forms in which the more general determinations are actually unfolded in different branches of social production.

The qualitative differentiation of individual capitals as the content of the 'chain' form of capitalist competition

In order to understand the foundation of the 'chain' or 'network'-form characterising the organisation of GVCs from a Marxian perspective, it is first necessary to establish the precise level of abstraction at which the phenomenon should be located. As Henry Bernstein and Liam Campling (2006, 439) note, the main focus of value chain analysis lies in the realm of the relation between individual capitals that, although belonging to what is commonly referred to as the same 'industry', actually comprises different individual branches of the (market-mediated) social division of labour, each of them producing a qualitatively different use-value. At the most general level, the relations that structure GVCs are thereby those of cross-branch competition. In other words, GVCs are predicated on the essentially indirect general social relation that regulates the establishment of the material unity of the social division of labour in capitalism. And yet, what makes up the peculiar character of GVCs as a form of capitalist competition is that they seem to give those indirect social relations the form of their opposite, namely, relatively enduring direct social relations of 'explicit co-ordination' that mediate the complex material interdependency between particular branches of social production through the configuration of 'chains' or 'networks' of capitalist firms. They do this by establishing 'how financial, material, and human resources are allocated and flow within a chain' (Gereffi 1994, 97). A further peculiarity of GVCs is that those forms of 'explicit co-ordination' involve power asymmetries of different degrees between the varied agents involved in them, which, in turn, redound in different profitability for each of the participants (Gereffi 2001, 1620).

Our claim is that the GVC approach is ill-equipped to explain this phenomenon. In effect, as argued at length elsewhere (Starosta 2010a), GVC analysis simply assumes the power differential among capitals and then 'explains' the emergence and dynamics of commodity chains on that basis, as the strategic choice made by lead firms through which they arbitrarily impose the conditions for the overall circulation (hence valorisation) of all other capitals along the chain. But although this might be descriptively accurate, it simply presupposes that all other capitals do not have the power to contest that organisational leadership and will therefore have no choice but submissively to accept to valorise at a lower rate of profit. This inability to provide a sound explanation of its very object of inquiry has accompanied the GVC approach from its world-systems origins, broadly based as it was in 'Monopoly Capital' theory.[2]

We think that the Marxian critique of political economy can provide firmer foundations for the comprehension of the nature and dynamics of GVCs. More concretely, the fundamental question lies in the connection between the essentially indirect nature of the general social relation that regulates capitalist production, and the varied direct social relations through which the establishment of the unity of the former is eventually mediated at particular nodes of the social division of labour. In other words, what needs to be uncovered is the inner connection between the self-expansion of capital on an ever-increasing scale through the unfolding of the 'law of value' (the content) and the relatively enduring direct social relations between particular individual capitals within a chain, whether relations of command or, in some cases, co-operation (the form). This connection, we argue below, is precisely what the Marxian 'law of value' can help elucidate. Let us expand and reframe this problem by first looking more closely at the general nature of capital.

One of the most potent scientific discoveries of Marx's critique of political economy was that capital is neither simply a thing (for example, the instruments of production), nor a productive unit or legal entity (i.e. a firm), nor a social grouping sharing common characteristics and interests (i.e. 'business' or 'the bourgeoisie'). In its general determination as self-valorising value, capital actually is a materialised social relation between commodity owners differentiated into social classes which, in its fully-developed form as total social capital, becomes inverted into the very (alienated) subject of the process of social reproduction and its expansion in its unity (Marx 1976, 763). Thus, capital is essentially the movement of self-expansion of the objectified general social relation between private and independent human beings which, in its own process, produces and reproduces the latter as members of antagonistic social classes (Marx 1976, 723–24; 1992, 185). Subsumed under the capital-form, the alienated content of social life becomes the production of surplus value or the formally boundless quantitative progression of the general reified form of social mediation (Marx 1976, 257).

Although this content governs the movement of capital as a whole or as an alienated collective power, the total social capital is nonetheless the product of the private and independent form taken by social labour. The general unity of the movement of the total social capital cannot be established immediately. It is thereby indirectly established through the exchange of commodities resulting from the apparently autonomous actions of individual capitals in competition with each other, as each of them pursues the maximisation of its profitability through the expanded reproduction of their formally independent cycles of valorisation. More specifically, the concrete form in which individual capitals assert their class unity as 'aliquot parts' of the total social capital is the process of formation of the general rate of profit (Marx 1991, 298–300, 312). This is the inner or essential determination of the general social relation between capitalist firms. However, the concrete realisation of this inner determination could be mediated under certain circumstances by the establishment of relatively stable direct social relations between certain individual capitals; for instance, relations of hierarchy and power such as those that structure GVCs. The elucidation of those determinate circumstances is precisely what a critical investigation of the social constitution of GVCs should be directed towards. The intellectual challenge, then, is to comprehend the differentiation of the valorisation capacities of individual capitals along the chain as an expression of the global unfolding of the 'law of value', that is, through the formation of the general rate of profit.

In volume 3 of *Capital* Marx develops the social processes regulating inter-branch competitive relations through his discussion of the formation of the general rate of profit and the 'transformation of values into prices of production'. The problem is, however, that Marx's argument in those pages seems to provide the contemporary reader with no elements for the comprehension of the cross-branch hierarchical relations between individual capitals of differential profitability and power characterising GVCs. In effect, as Marx argues, the *formation* of the *general* rate of profit takes the concrete form of a tendential *equalisation* of *average* rates of profit across the different branches of the social division of labour. And yet, several pages later, more precisely in the context of a discussion of the genesis of capitalist ground-rent, Marx (1991, 940ff.) hints at a social phenomenon that can shed light on the nature of GVCs. Specifically, when he is discussing the peculiarities of small-scale peasant ownership, Marx unfolds the category of 'small capital' and shows that its valorisation is not regulated in the same form as normal capitals. Now, whilst Marx only develops those arguments in the specific context of agrarian capital (that is, industrial capital valorised in agriculture), the work of Juan Iñigo Carrera (2016) insightfully shows that their applicability is broader and can be generalised to industrial capital as a whole.

As Iñigo Carrera argues, normal capitals are defined by Marx as those that reach the specific magnitude that 'is required in each line of business to produce commodities at their price of production' (Marx 1991, 843). In other words, these are the individual capitals that have the concentration needed to set into motion the socially normal methods of production and that therefore *actively* participate in the formation of the general rate of profit. Small capitals, however, do not reach that scale and are therefore unable to take a direct part in the tendential equalisation of the rate of profit at the normal general level. By contrast, their rate of valorisation in non-agricultural branches of production is usually regulated by the rate of interest (generally lower than the normal rate of profit) that those capitals of restricted magnitude could yield if they closed down the business and were turned into interest-bearing capitals (Iñigo Carrera 2016, 26).

This means that although these capitals do not have the scale to keep up with the development of the productivity of social labour required to survive the competitive battle, they nonetheless have the chance to extend their agony by compensating their higher production costs with their lower rate of profit. The limit to the survival of small capitals is thereby given by the extent to which the price regulating their valorisation (determined by the cost price of their inputs plus the interest rate on the liquidation value of their respective assets) manages not to rise above the price of production regulating the valorisation of normal capitals. What is more, if the price that regulates the valorisation of small capitals is actually lower than the normal price of production that regulates the valorisation of normal or average capitals, the latter become effectively excluded from those branches of production. This is what explains the resilience and even dominance of small capitals in particular branches of production despite the general tendency for the concentration and centralisation of capital that characterises the capitalistic accumulation process.

The reproduction of small capitals has another implication which is crucial for the comprehension of the formation of value chains: the release of surplus value by small capitals (Iñigo Carrera, 2016, 28ff.). If concrete circumstances are such that small capitals manage to sell their commodity at a price that stands above the one determined by their specific rate of valorisation but below the price of production of normal capitals, then a potential surplus profit emerges. However, although this surplus profit is borne by the commodities produced by small capitals, their competition over that extraordinary mass of abstract social wealth eventually leads them to expand production and drives their prices down to a level determined by their specific rate of valorisation. Does this mean that the surplus profit vanishes into thin air? Certainly not. Although it slips through the fingers of small capitals, it ends up in the hands of some of the normal capitals that operate in directly neighbouring branches of the division of labour and with which they relate in the sphere of circulation. Assuming, for the sake of argument, that small capitals are suppliers of inputs for those normal capitals, the latter will benefit from a permanent flow of extra surplus value derived from the purchase of inputs at prices below their normal price of production whilst selling their own commodities at their full price of production. In turn, this means that those successful normal capitals that end up monopolising the market relation with small suppliers will systematically obtain a higher-than-normal rate of profit. We shall term the latter ‘enhanced normal capitals’.

In brief, a stratification of individual capitals with differential valorisation powers emerges out of the immanent dynamics of competition that mediate the indirect establishment of the unity of social capital as the concrete subject of the exploitation of the collective labourer. Two important points should be emphasised in this regard. First, this is not simply a short-term phenomenon but can reproduce itself over relatively long periods of time. Still, this differentiation cannot persist indefinitely, as the aforementioned objective limits to the reproduction of small capitals are reached.

Secondly, this process of differentiation does not constitute, as theories of ‘Monopoly Capital’ would have it, the transcendence of the formation of a general rate of profit as the fundamental law governing the competition between individual capitals. Rather, it involves a further mediating instance in the realisation of that very same law. The realisation of the identity of individual capitals as ‘equally valorised values’ (hence the tendency for the equalisation of their individual profit rates) (Iñigo Carrera 1995), is further developed in the form of its opposite, that is, through the sustained inequality of their valorisation capacities predicated on the extended reproduction of small capitals. In this sense, the differentiation of individual capitals is a more mediated form in which they assert their class unity as particular organs of the concrete subject of the accumulation process (and hence of the exploitation of the collective labourer as a whole): what Marx termed the total social capital (Marx 1991, 297). This means that although the establishment of the concrete rate of profit of each capital in a ‘value chain’ is mediated by their respective exercise of power in the sphere of circulation (thereby *appearing* as the immediate outcome of those unequal market relations), it is in reality strictly and objectively-determined in accordance with the ‘macro’ dynamics of capital accumulation as whole. Power asymmetries are not the cause but an expression of profit rate differentials.

In our view, this process of differentiation of individual capitals can help elucidate the essential nature of GVCs. Succinctly put, the inner content underlying the constitution of GVCs is the appropriation by certain normal capitals of the surplus value released by small capitals. The deeper *immanent purpose* and *prime-mover* of the outsourcing of manufacturing is therefore the *multiplication* of the sources of extra surplus value released by small capitals in the sphere of circulation. Thus, although it is true that one of the conscious motives for normal capitals to engage with small capitals in commodity chains is the benefits to be obtained by the employment of ‘cheap labour’ in low-wage locations or non-unionised sectors, this line of reasoning simply assumes that those lower costs will not (entirely) translate into higher profits for contractors or suppliers but will be appropriated by ‘lead firms’. The determinations of the law of value developed above explain why this will necessarily be the case: although normal capitals are not the direct employers of those low-wage workers, they nonetheless end up appropriating part of the surplus value that corresponds to their exploitation.

The same could be said of ‘organisational flexibility’ which, as Raikes, Jensen and Ponte (2000, 396) highlight, tends to be flexibility for the key agent in the chain. From the perspective of the organic unity between the production and circulation of capital, ‘organisational flexibility’ actually entails the optimisation of the overall turnover structure of normal capitals at the expense of higher circulation costs for all other capitals in the chain (through, for instance, accumulation of inventories or unfavourable conditions of commercial credit). More generally, the transfer of surplus value in the chain will always be mediated through the establishment of determinate conditions of turnover for each participating capital, since it is out of the whole cycle of valorisation (i.e. production plus circulation) that their respective concrete annual rate of profit emerges. In other words, the ability of chain drivers to take advantage of wage differentials and 'organisational flexibility' is the reverse side of the inability of small capitals to retain any potential extraordinary profits due to their inherently limited valorisation capacity.

The *general* nature of both the composition and governance structure of GVCs also follows from the differentiation of industrial capitals outlined above. Thus, although varying in its specifics with the particularities of each GVC, it seems reasonable to suggest that all commodity chains generally comprise at least three qualitatively different kinds of capitals: enhanced normal capitals, normal capitals and small capitals. The peculiarities of the governance structure will surely vary according to the composition of the chain. Whilst stricter relations of command/subordination will tend to prevail in nodes where exchange relations between normal and small capitals dominate, more 'horizontal' relations will tend to prevail among normal capitals and, to some extent, also between enhanced normal capitals and normal capitals. The simple reason for this is that more pronounced hierarchical relations are more likely to be the concrete mediating form involved in the appropriation of an extraordinary surplus value freed up by small capitals. In all cases, however, those varied direct social relations of command or co-operation remain forms taken by what essentially are indirect relations of competition through which the general articulation of privately-undertaken social production takes place.

The changing organisational forms of capitalist competition and the recent configurations of GVCs

The above explanation concerns the simpler dimensions of this phenomenon and therefore bears mainly on the early constitution of GVCs. However, as we shall discuss in more detail in the last section on the global automotive industry, there has been a significant organisational transformation in GVCs since the late 1980s. As already commented, these changes have revolved around two intertwined processes. The first is the tendency for a growing de-verticalisation of assemblers through the outsourcing of an increasingly wider array of productive functions, and their specialisation in product definition, development, and design. The second is the vertical re-integration along the rest of the supply chain, giving birth to the so-called automotive 'mega suppliers'. As argued elsewhere (Starosta 2010b), the electronics industry was another case in point in this sense, with an even more pronounced process of outsourcing of manufacturing to 'giant contractors'. In both branches of capitalist production, these changes were related to the progress of 'modularisation' in product architectures and production processes, although to different extents (MacDuffie 2013; Sturgeon 2002). The rising 'big' suppliers and contractors, unlike traditional simple parts producers, not only provide lead firms with more complex manufacturing activities (large subassemblies in the automotive industry and often final assembly in other branches like electronics), but also partake in an increasing load of product design and engineering. Moreover, they do not serve just or mainly one brand-name firm through a captive relationship, but tend to manufacture for many of them, and even from very different product markets. On this basis, first-tier suppliers and contractors have rapidly grown into global giant corporations in their own right, with production facilities dispersed worldwide.

Now, the main focus of GVC research on these transformations is the analysis of the conscious strategies undertaken by transnational corporations in order to (re)configure GVCs in the benefit of their own profitability. In fact, implicit in the notion of 'chain driver' or 'lead firm' put forward by the GVC approach is a conception that raises certain *individual capitals* to the status of concrete subjects of the process of accumulation within each value chain. However, as already stressed in this chapter, the constitution of the organisational relation between various individual capitals within chains results from the operation of the inner determinations of the process of capital accumulation. Therefore, the changing firm strategies that *appear* as determinants of the development of GVCs should be themselves grasped as products of those economic processes, i.e. as concrete forms that mediate those transformative dynamics. Thus, what is needed to grasp the real determinations behind the recent transformations of GVCs is a rigorous inquiry into the changes of the process of capital accumulation in general and, on that basis, their varied specific manifestations in each branch of social production.

In a nutshell, our approach suggests that these recent reconfigurations of GVCs should be seen as expressions of the unfolding of the process of differentiation of individual capitals and its limits discussed earlier. On the one hand, we have seen that it is the tendency for the concentration and centralisation of capital springing from the accumulation of the total social capital that ultimately undermines the competitive edge of small capitals. This is done by increasing the productivity of labour of normal capitals to the point where their price of production sinks below the price that regulates the valorisation of small capitals. On the other hand, in light of the particular attributes of 'mega suppliers' or 'giant contractors', it seems reasonable to consider them as normal capitals that have eventually managed to enter into (or, rather, grow within) branches of production formerly dominated by small capitals. Those are the general economic processes that account for the initial tendency for a fragmentation of the supply base into a mass of small capitals (as in the classic post-war US automotive industry) and its subsequent consolidation through the emergence of highly concentrated suppliers or contractors. In this sense, it is highly remarkable that the rise of mega suppliers in the automotive industry has been closely associated with the progress of the automation process in component and subassembly production (in some cases reaching 90 or 100%, see Krzywdzinski 2021). This was also the case of the electronics industry, where the automation of circuit-board assembly helped to trigger the emergence of turn-key contract manufacturing (Sturgeon 1998, 12–14). These technical changes involve outlays of capital and productive scales that are beyond the potentialities of smaller capitals.

As mentioned above, although these dynamics have taken shape through a decrease of power asymmetries between lead firms and their suppliers, the former have retained the 'leadership' function in the chain. As scholars from the systems integration literature have argued (Brusoni and Prencipe 2001; Jacobides et al. 2016), lead firms 'know more than they actually do', that is, they retain a broader and broadening knowledge base than what they concretely need to perform their particular special function in the division of labour within a chain, namely, conceptual product design and definition (automakers, as already stated, have so far also retained final assembly). The reason for this is that this broader 'knowledge base' is required for lead firms to undertake the necessary overall conscious co-ordination of the deeper material or technological interdependencies along a chain emerging from modular product architectures and the possibilities of separation of design and manufacture that they entail.

This systems integration approach provides very interesting insights on the continuous need for an element of conscious organisation of the social division of labour within value chains, in spite (or rather, because) of the undeniable trend towards the vertical disintegration of design and manufacture. However, as happens more generally with the evolutionist/neo-Schumpeterian tradition of which these authors are part, this research is one-sidedly focused on the material or technological dimension of capitalist production and overlooks its specific social form, namely, the subordination of the production of useful things or use-values to the production of surplus value (Smith 2004, 220–26). From a Marxian perspective, then, all those technical-organisational processes must be grasped in their contradictory unity with the value processes that shape the dynamics of capitalism (Gough 1996, 2067).

In this sense, the resilience of authority relations within chains beyond what GVC analysts recognise is not simply predicated on the technical/material necessity for overall systems integration. Direct command by lead firms also persists because of the irreducibly antagonistic social relations between private producers on which these networks are based, even if they entail a limited socialisation of production cutting across formally autonomous individual capitals (Gough 1996, 2072–73). This general nature of inter-firm relations acquires a peculiarly intensified expression due to the growing vertical disintegration between product development and manufacturing. Specifically, albeit in varying degrees according to the extent of outsourcing, the lead firms' invested and valorised capital can only exist materialised in commodities which are the outcome of the manufacturing activity, and hence the immediate possession, of suppliers or contractors. Similarly to the capitalist's need to ensure through their command in the direct process of production that the worker does not expend more than socially necessary labour-time during the working day (Marx 1976, 303), brand-name firms need to ensure that the outsourcing of manufacture to suppliers does not compromise the completion of the turnover circuit of their own capital in at least the socially normal time and conditions for the respective branch of production.

The function of brand-name firms as systems integrators also impinges on the concrete forms taken by the formation of the general rate of profit through which all individual capitals assert their unity as organs of the total social capital. In the first place, it is to be noted that the organisational separation of product design and manufacture is premised on technological innovations by brand-name firms themselves that make it materially feasible to 'codify' and transmit more easily objectified design knowledge, so that it can be passed over more smoothly and cheaply from designer to producer (e.g. the use of simulation technology and modelling in Computer Aided Design and, more generally, the use of Information and Communication Technologies to transfer digitised information and to instantly monitor subsequent production) (Krzywdzinski 2021, 510–16; Pavitt 2003, 84). These material prerequisites for outsourcing do not fall from the sky but are the result of the competitive strategies of lead firms. The fundamental active agent in this regard is the brand-name firm searching for cost reductions *vis-à-vis* its competitors by benefiting from the multiplication of economies of scale by suppliers, which have become normal capitals specialised in manufacturing services.

This means that the reconfiguration of value chains through outsourcing to mega suppliers and giant contractors must be seen as a concrete form taken by the production of temporary surplus profits from innovations by brand-name firms through the general mechanisms described by Marx (1976, 433–35; 1991, 338), that is, by allowing early innovators to sell at individual prices that stand below the socially general ones ('prices of production') until the innovation becomes universal and the surplus profit is eroded. The renewed outsourcing of additional functions by lead firms recreates the generation of a surplus profit. In this way, the socially necessary labour for the reproduction of the class of wage-labourers indirectly diminishes and relative surplus value is produced by capital as a whole. This role of technical and organisational innovations as a source of surplus profits for certain individual capitals (and hence of relative surplus value for the total social capital) provides further objective social foundations for the persisting dominance of lead firms in the governance of value chains. In this sense, GVCs are not simply technical linkages with superimposed direct relations of conflict over so-called 'value capture'. Rather, they are *chains of production of surplus value by the total social capital*, in which 'lead firms' assume the prominent role in the pursuit of surplus profits, in turn, determined as a concrete form of the production of relative surplus value.

The reproduction of the leadership of brand-name firms in GVCs also bears on the question of the appropriation of the surplus value released by small capitals in the sphere of circulation. The rise of mega suppliers has not led to the total elimination of small capitals in the value chain; the latter remain in the branches of the industry that produce the still necessary simpler parts or components. Indeed, precisely part of the appeal for lead firms of the multi-tier system of suppliers is the overtaking of component purchase by mega suppliers (Wong 2017, 22–23). This means that, in their condition as normal capitals, mega suppliers would be in a position to control to their own benefit the direct relationships with small component suppliers in the sphere of circulation that necessarily mediate the said transfer of surplus value. However, riding on the objective social power derived from their role as 'systems integrators', brand-name firms will most likely maintain their 'entitlement' to the surplus profit freed by the remaining small capitals in the chain, even though they are no longer the individual normal capitals with whom the latter directly relate in circulation. In this way, they reassert their qualitative condition as enhanced normal capitals in their respective value chains.

In the next section, we shall move from the consideration of the differentiation of individual capitals to the changing forms of exploitation of the collective labourer by the total (global) social capital. This will allow us to look at the other constitutive dimension of value chains, namely, their global character.

GVCs and the international fragmentation of the subjective productivity of the working class

The production of relative surplus value in the form of large-scale industry, and particularly the computerisation and robotisation of the production processes since the microelectronics revolution, entails a three-fold qualitative differentiation in the evolution of the labour-power of the members of the collective worker.[3] In the first place, these transformations have involved the *expansion* of the productive attributes of those wage-labourers performing the more complex parts of the labour process, that is, all those forms of (mainly) intellectual and scientific labour which are required for the leap forward in the automation of the system of machinery, including its technological applications and practical co-ordination. In the second place, these novel technological forms entailed a further step in the expulsion of the intervention of the human hand and of the experience-based practical knowledge of workers in the labour-process *vis-à-vis* the forms dominating during the previous historical cycle of accumulation. Indeed, these productive changes have accelerated the codification of tacit knowledge, previously embodied in the manual industrial worker and largely acquired through lengthy on-the-job, learning-by-doing processes. Once codified, this knowledge has been objectified as an attribute of the system of machinery (Huws 2006). In this sense, the tendency has been certainly one of 'deskilling' or 'degradation' of direct production work, although not as a result of the furthering of the manufacturing division of labour, as Fröbel et al. (1980) would have it, but through the objectification of formerly manual tasks as automated functions of machines. In the third place, whilst the new technologies have not resulted in the total elimination of manual labour from automated processes of production (Alcorta 1999, 164), they have recreated the conditions for the extended reproduction of what Marx (1976, 588ff.) called the modern manufacturing division of labour, that is those non-mechanised tasks and labour processes acting as an 'external department' of large-scale industry proper as the dominant form.[4]

The social processes described above have arguably been at the heart of the recent mutations of GVCs through the rise of highly concentrated suppliers and contractors. In formally fragmenting the functional extraction of surplus value from the different organs of the collective labourer through the organisational de-coupling of design and manufacturing, the latter facilitates the exacerbation of the differentiation of the conditions of reproduction of labour-powers of heterogeneous complexity. Whilst lead firms tend to concentrate mainly on the exploitation of the most expanded forms of productive subjectivity needed for fundamental R&D productive activities, suppliers and contractors tend to exploit the part of the collective labourer of less complex productive attributes. Although the latter do employ a number of engineers, technicians, administrative staff and so on, that might embody a labour-power of considerable complexity (but still, on average, of less complexity than the kind of labour-power employed by brand-name firms), the proportionally larger mass of their workforce is composed of workers bearing the degraded kind of labour-power that acts as an appendage of a system of machinery in highly automated labour processes or, worse, that performs detailed manual tasks in whatever phases of direct production remain that are still subject to what Marx termed a manufacturing division of labour.

Through this organisational fragmentation of the production process, capital undermines one of the material bases for the political unity of those two different organs of the collective labourer in the struggle over the value of labour-power: the fact of being exploited by the same individual capital. In this way, capital economises on the total variable capital advanced by widening the differentiation between the value of the more expanded and more degraded kinds of labour-power. The latter becomes simply determined at a level that reflects –at best– the reproduction of those immediate productive attributes needed to be employed as an appendage of the machine or a specialised labourer (Iñigo Carrera 2013, 74). By contrast, in situations where the two kinds of productive subjectivity are exploited under the same 'juridical roof' (that is, the same firm), less skilled workers are in a better position to force capital to provide a certain degree of universality in the conditions of reproduction of the collective labourer as a whole.

The role of the differentiation of individual capitals in accentuating the fragmentation of the conditions of reproduction of workers is not restricted to that between lead firms and first-tier suppliers. The presence of small capitals in the value chain plays its part as well. Despite the accelerated and pronounced process of concentration and centralisation of capital at the level of manufacturing, small capitals still subsist in the production of less complex components, basic inputs, and raw materials. As Iñigo Carrera (2016, 31–32) points out, the precarious situation in which these capitals operate makes them generally prone to the most ruthless exploitation of the workers they employ. However, the unleashing of the potentialities of the new organisational forms of GVCs for a further deepening of the differentiation of the working class was burdened with another materially-grounded political barrier. In effect, the so-called Keynesian phase of capitalist development was based on the relatively universal reproduction of the two general types of productive subjectivity, that is expanded and degraded. The material basis of this form of working-class reproduction was the following: however degraded the subjectivity of direct labourers was during this phase of capital accumulation, it still retained a strategic productive intervention at the heart of the production of relative surplus value, that is in the production of machinery itself (Iñigo Carrera 2013, 61ff.). In effect, both the calibration of machinery and the assembly process still depended on the subjective expertise of direct workers. This strategic intervention gave the degraded organ of the collective labourer a particular source of political strength in the struggle over the value of labour-power, which allowed those workers to force capital to moderate the differentiation of their conditions of reproduction *vis-à-vis* those performing more complex forms of labour.

In order to spread the accentuated differentiation of the conditions of reproduction and exploitation of the varied organs of the collective worker, capital thereby had to break up the unity that the working class had achieved as an expression of those determinations of the prior historical cycle of accumulation. The very dynamics of the unfolding of the so-called New International Division of Labour (NIDL), mediated as they were by the general crisis of overproduction of capital on a world scale that exploded in the mid-1970s, provided the means through which such a process of restructuring could push forward (Iñigo Carrera 2013, 70–74). In the first place, in eroding the need for the strategic manual intervention and/or practical knowledge of direct labourers in the production process of machines, the microelectronics-based automation of the labour process at the basis of the development of the NIDL undermined the material source of the political power of this segment of the working class. This situation was further compounded by the real or potential shift of the valorisation process that, as we have seen, this technical change made possible. In the second place, working-class solidarity was weakened even further through the disciplinary effects of the growth of the relative surplus population in most advanced capitalist countries, brought about by the open manifestation of the said global crisis of overproduction (whose definitive resolution has been postponed ever since through successive cycles of credit-fuelled expansion) (Iñigo Carrera 2013, chapter 6). Thirdly, the concomitant crisis of 'national developmentalism' in the Global South and of the 'Soviet Bloc' in Easter Europe also swelled the ranks of the relative surplus population.

On these material and social bases, Transnational Corporations (TNCs), acting as lead firms and pushing for the constitution of geographically dispersed global value chains, were one among different concrete agents driving this transformation, in a complex process which has also been mediated by the 'emergence' of 'national' capitals from the 'periphery', state policies and workers' struggles. As Fröbel et al. (1980) rightly (though one-sidedly) captured in the late 1970s without being able to uncover its general content, this social process of global restructuring historically started with the geographical relocation of simple manual labour processes to low-cost countries and regions, whilst concentrating its increasingly more complex parts in the more 'advanced' national or regional spaces of capital accumulation. However, subsequent historical developments revealed that those simple original forms of the NIDL have evolved into a more complex constellation, whereby capital searches for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class (through their impact upon their general conditions of reproduction and condensed in the so-called 'historical component' of the value of labour-power). Each country, therefore, tends to concentrate a certain type of labour-power of distinctive 'material and moral' productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital in the least costly possible manner. In this context of exacerbated competition among wage-workers, capital can, therefore, economise on the overall capital advanced for the total wage bill, lengthen total working hours and increase the average intensity of labour. Thus, out of all those different antagonistic social actions, but 'behind the back' of the diverse agents involved, a reduction of socially necessary labour-time for the reproduction of class of wage-labourers as a whole result and, as a consequence, relative surplus value is produced on a world scale.

The significance of the above transformations of the international division of labour for the comprehension of the inner determinations of GVCs should be obvious. For it is clear that the formation of GVCs not only expresses the formal differentiation of capital into individual capitals of stratified valorisation capacities; in addition, they mediate the international fragmentation of the productive subjectivity of the collective labourer of large-scale industry.

The global automotive industry in light of the organisational and spatial reconfigurations of GVCs

The post-war US automotive industry constitutes a good example of the *simple form* of value chains, i.e. one which is comprised of one normal capital that becomes 'enhanced' by virtue of its relationship with a multitude of small capitals in the supply base. This classic system of supplier relations entered a phase of deep restructuring since the mid-1980s. Partly as an answer to the rise of Japanese auto firms as challenging competitors on the world market, the same 'lead firms' that in the post-war decades fuelled the proliferation of a myriad of small capitals (Helper 1991, 797ff.), started to foster the centralisation of capital in parts and component production by way of mergers, acquisitions and even by the spin-off of component divisions from assemblers themselves (Frigant 2009; Humphrey 2000, 248–49). By increasing the division of labour with the creation of this new 'subassembly' branch of social production, assemblers were pushing for increasing scales of production that would, in turn, allow to introduce better technologies (particularly, to increase automation, see Jacobides et al. 2016, 1950). In terms of our previous analysis, they were searching for surplus profits through technical and organisational innovation. As a result, the reconfigured value chains were more complex than its classical post-war version. At the risk of a slight oversimplification, if until the 1980s there arguably was only one (enhanced) normal capital which related in circulation with a multiplicity of small capitals as suppliers, the globally-restructured value chain involved at least three types of capitals: enhanced normal capitals as chain drivers, normal capitals as mega suppliers and small capitals in the lower tiers of the supply base.

It is our contention that mega suppliers might be seen as normal capitals which, precisely by virtue of that emergent novel determination, are now able to push forward technical change in complex parts manufacturing. In effect, as mega suppliers developed and consolidated, they started to cater for several assemblers, thus significantly expanding volumes of production. This, as Volpato (2004, 169) reports, was a conscious goal of lead firms when they outsourced subassembly production. Indeed, the increased scale is one of the crucial advantages of the very existence of 'mega suppliers' within the chain, as they can share facilities, machinery, and platforms between different 'customers', in contrast to the necessarily more limited scope of in-house production by assemblers themselves. Besides, we saw that the concentration of capital at the level of parts and component producers implied a decrease in power asymmetries between assemblers and the now larger suppliers. Moreover, the relatively high complexity of subassemblies required an increased bidirectional flow of information between both types of firms in the process of component co-design. However, despite the greater 'horizontality' of relations between firms and the need for more co-ordination across the chain, mega suppliers remain in a relatively subordinate position *vis-à-vis* lead firms.

As various scholars close to the GVC approach have argued (MacDuffie 2013; Sturgeon et al. 2008, 307–8; Volpato 2004, 176–77), this latter fact reflects the strong technical need for a 'system integrator' implied in the product architecture of motor vehicles (for example, the high functional interdependence between modules). But at least of equal relevance for the continuity of the dominance of assemblers is the persistent differentiation in the 'upper' segments of the chain between assemblers as *enhanced normal capitals* and mega suppliers as *normal capitals*. More specifically, despite the undeniable concentration and centralisation of capital in the first tier of the supply base, the former firms remain 'entitled' to the appropriation of any potential surplus profits that might arise in the rest of the chain. This will certainly include the extra surplus value released by the remaining small capitals in the lower tiers of the supply base. But assemblers will most likely also profit from the lower wages paid by component producers, including the novel mega suppliers. This should come as no surprise. In effect, had assemblers not proven able to reap a substantial share of the emerging benefits of the transferring of productive functions to mega suppliers, they would not have *deliberately* encouraged and fostered this wave of outsourcing in the first place.

In this sense, it is also worth bearing in mind that, as argued earlier, the ensuing differentiation in the conditions of reproduction of wage-workers was determined by the fragmentation of the exploitation of the varied organs of the collective labourer across different individual capitals (in contrast to the 'vertically integrated' extraction of surplus-labour in-house). Thus, this need to differentiate between individual exploiters of the collective labourer of the chain was exacerbated by the increasing share of highly trained (and therefore more expensive) workers in the assemblers' workforce. In fact, the process of outsourcing of subassembly production to mega suppliers resulted in a further specialisation at the top of the chain, allowing assemblers to invest a greater portion of their capital (hence also gaining scale) in design, innovation and 'system integration' functions, which were now regarded as their 'core competence' and as 'high value-added' activities (i.e. more profitable than direct manufacturing). These functions required such a massive scale to the point of exceeding the reach of most mega suppliers (Jacobides et al. 2016, 1960).

This is reflected as well in the clear-cut size difference in the magnitude of capital between assemblers in general and the largest suppliers.[5] Remarkably, it seems significant that despite the accelerated process of concentration and centralisation of capital among first-tier suppliers in recent decades, this scale disparity has remained firmly in place. In effect, whenever the size of the relatively smaller assemblers approached that of the largest mega suppliers, a process of mergers or 'alliances' between assemblers tended to ensue.[6] In other words, whenever those assemblers seemed to have fallen behind in the process of concentration of capital and were thus 'dangerously' approaching the apparent lower limit to be a normal capital in this branch of social production, the process of centralisation of capital restored their status as enhanced normal capitals, reinstating at the same time the 'entry barrier' in the assembly sector. This strongly suggests that the magnitude of capital required to act as a 'chain driver' in the automotive industry is still out of reach for most suppliers, even after the notable concentration of capital in the sector during the last decades. On this basis, assemblers maintained dominance over the chain, essentially expressing their character as 'enhanced' normal capitals *vis-à-vis* normal and small capitals.

Let us now recapitulate the fundamentals of our account of the recent process of restructuring in the automotive value chain. Organisational changes in the sector had a two-fold determination. First, they were a form of ramping up scales of production both on the assemblers' side (via specialisation in innovation, design, and system integration) and at the supply base (through vertical re-integration of manufacturing). Second, they mediated the process of differentiation in the conditions of reproduction of workers. In both cases, although the immediate beneficiaries were the individual capitals directly involved in the chain (and particularly among them the 'enhanced' normal capitals acting as 'chain drivers'), the essential outcome was the production of relative surplus value for the total social capital through the cheapening of labour-power. The new wave of 'globalisation' of the industry since the 1990s was certainly related to the first of these determinants of novel GVCs, for the consolidation of mega suppliers as normal capitals was closely associated with their global expansion as they followed the assemblers' own internationalisation. In this sense, global mega suppliers were able to 'solve' the contradiction between local sourcing for each assembly plant and economies of scale, by means of centrally-producing common components and then assembling customised modules close to terminals (Humphrey 2003, 125; Sturgeon et al. 2008, 306). In this way, mega suppliers could also fulfil their role as 'lieutenants' of assemblers (Wong 2017, 22) in managing the rest of the supply chain, i.e. the lower tier suppliers that were in most cases less global than mega suppliers.

But as we argued in section 3, the main driver of the globalisation of automotive value chains was the evolving NIDL structured around the international differentiation of productive attributes and costs of wage-workers. In fact, mega suppliers were particularly aggressive in their location strategies, establishing their centralised component production in low-wage sites, especially with regard to those more labour-intensive activities (Frigant and Miollan 2014; Sturgeon et al. 2008). Instead, assemblers kept a large portion of the labour-force at their home countries, mainly because design and research activities remained located at, or near, the traditional headquarters of these companies (and because they continued to assemble locally to serve a portion of domestic demand). This is not to say that assemblers were inimical to the NIDL; the point is that mega suppliers played the role of active agents in the relocation of manufacturing activities within the chain (Frigant 2009, 433ff.; Frigant and Zumpe 2017, 81). Indeed, it can be said that the rise of mega suppliers has been a concrete and necessary form of the international fragmentation of the productive subjectivity of the working class, since they have been the most prominent *direct* exploiters of cheap labour in 'low-cost' locations. Of course, it should be obvious at this stage of our argument that assemblers, as chain drivers, have managed to take a share in the resulting surplus profits.[7]

Conclusion

In this chapter, we have offered an alternative account of the nature of the articulation of individual capitals in capitalist global production of commodities, i.e. the so-called GVCs. This approach, we think, provides a sounder explanation of the most salient phenomena at stake than those offered by the more widespread GVC literature. In brief, we have shown that the different profitability of the various types of firms comprising the chain is actually an expression of the differentiation of individual capitals, resulting in turn from the realisation of the 'laws of motion' of capitalist production, i.e. of the law of value. In this sense, these chains are not simply an articulation of firms on the basis of direct social relations of power and command, but chains of production of surplus value that realise the indirect nature of capitalist social relations. As such, they mediate the unfolding of the process of concentration and centralisation of capital through which the latter asserts itself as the alienated subject of the development of the productive forces of society.

In this inquiry, we threw into relief what could appear as a somewhat striking development: the recent transformative dynamics of GVCs *seem* to imply the 'de-centralization' of capital, since the process of outsourcing effectively splits innovation from manufacturing into the core activities of different individual capitals, on top of the already fragmented manufacturing phase itself across the supply chain. Although this development has been a concrete form of expanding the scale of *both* phases of the material unity of the process of production of commodities, it remains true that the novel form of GVCs has very clear objective limits from the point of view of the development of the productive forces of society, a point which has been mostly overlooked by GCV scholars. In particular, the efficiency gains of outsourcing of manufacturing are conditioned by the extent to which mega suppliers and contractors achieve economies of scale deriving from the fact that they can cater for several lead firms. However, what scholars have not mentioned is that those economies of scale will tend to decrease as the centralisation of capital in final products markets leads to the shrinking of the pool of potential customers. Eventually, vertical 'reintegration' of innovation and the several phases of manufacturing will prove more conducive to the increase in the productivity of social labour and hence to the production of relative surplus value, thus making necessary yet a further leap forward in the concentration and centralisation of capital in the automotive industry.

Appendix

The rate of profit in the automotive industry

The transformations in the global automotive industry leading to the configuration of GVCs can be appreciated through the analysis of the profit rate of the different individual capitals that comprise the chain. The classical form of supply relations in this industry consisted in the association of normal capitals in the assembly sector with small capitals in the supply base. Table 8.1 shows the profit rate on own capital for the US automotive sector between 1947 and 1965.

These data show a clear differentiation in the profit rate between assemblers and suppliers, which is consistent with the differentiation of individual capitals discussed in this chapter. It should be noted that the difference is greater when only the 'Big Three' automakers (General Motors, Ford and Chrysler) are taken into account, although it is also apparent if all assemblers are considered.

The contemporary reality of the global automotive industry is shown in Table 8.2. During the period 1992–2019, the average profit rate of the 12 largest

Table 8.1 Profit rate on own capital in the US automotive industry

Years	*'Big Three' Assemblers*	*All Assemblers*	*Part Suppliers*
1947–1965	25.0	20.2	13.8

Source: Net income (after tax) as a percentage of net worth reported by Crandall (1968).

Table 8.2 Profit rate on own capital in the global automotive industry

Years	*Top 5 Global Assemblers*	*Global Assemblers (13 Firms)*	*Global Mega Suppliers (Top 10 by Sales)*
1992–2000	14.1	8.6	12.4
2001–2010	7.5	8.2	5.8
2011–2019	15.3	12.0	15.3
1992–2019	12.1	9.6	11.0

Source: Net income (after tax) as a percentage of net worth. Own calculations based on balance sheets and U.S. Census Bureau (2022).
Note: years with negative net worth are excluded.

global assemblers was essentially the same as the average profit rate of the 10 largest global suppliers, in both cases ranked by global sales. Despite the inherent difficulties of the measurement of the profit rate, the tables seem to support our characterisation of 'mega suppliers' as normal capitals.

Notes

1 'Lead firms', in GVC parlance, are those firms that 'drive' the chain (thus the similar term 'chain driver'). They include, for instance, final assemblers in the automotive industry and, more broadly, 'brand-name firms', which include other 'lead firms' in branches like electronics or apparel. We shall use all these terms interchangeably in the rest of the chapter.

2 More recently, GVC scholars have broadened the original notion of chain governance by incorporating other actors besides capitalist firms (Ponte et al. 2019), thereby providing a more nuanced classification of the 'types of power' observed in GVCs (Ponte et al. 2019). However, as these scholars themselves highlight (2019, 135), this typological approach remains just an analytic guide to the empirical research of particular GVCs rather than a proper theoretical framework. At the same time, a new critical strand of GVC scholars aims at further expanding the scope of the GVC approach to include dynamics of subordination and exclusion as constitutive moments in a process of uneven development (Bair and Werner 2011; Werner and Bair 2019). While these modifications in the approach may enhance its descriptive accuracy, they are still unable to solve its more deeply-entrenched incapacity to uncover the inner determinations that explain the very existence of power relations as concrete forms of realisation of capitalist competition between firms. In contrast, some recent contributions to the GVC debate from perspectives close to the Marxian critique of political economy have emphasised the need to ask *why* firms 'innovate, reorganise or relocate' within GVCs, rather than *how* (Havice and Pickles 2019, 177). However, besides some sharp observations about the striking lack of conceptualisation of the very concept of 'value' within the GVC approach (Gradin 2016), there has not been much progress in showing precisely how a solid grasp of the Marxian law of value could help elucidate the underlying determinations of the concrete forms of articulation of individual capitals in the chains. For instance, in one of the most elaborated attempts, Quentin and Campling (2018, 36) state that the purpose of value theory is merely to provide an objective parameter to detect 'potentially arbitrary money flows' and therefore to expose situations in which the law of value does *not* rule the relations between firms. In contrast, we think that from the standpoint of the Marxian critique of political economy, the task is concretely to demonstrate why and how the very operation of the laws that regulate the movement of capitalist competition leads to unequal valorisation capacities of individual capitals and, therefore, to different forms of 'capture' or transfer of value within the chain.

3 This is a summary of the main aspects of this process which are more relevant for the purpose of this chapter. For a more detailed account, see Starosta (2016).

4 Strictly speaking, the multiplication of the surplus population relative to the needs of the accumulation process has also constituted a transformation of productive subjectivity produced by the automation of large-scale industry (see Marx 1976, 533–75).

5 As expressed by different balance sheet measures like total and fixed assets and net worth.

6 Take, for example, the cases of the strategic alliance between Renault and Nissan, the creation of the FCA group upon FIAT's acquisition of Chrysler and, more recently, the formation of the Stellantis group through the merger between FCA and PSA. All these

cases involved relatively large firms which had lagged behind *vis-à-vis* the scale of the leading individual capitals with the greatest share of global output.

7 It should be noted that, although the search for a cheap and compliant labour-force across the globe by the total social capital can be traced back at least to the post-war internationalisation phases of the automotive industry (Fitzsimons 2020; Grinberg 2011, chapter 3), this form of the international division of labour has recently intensified through the 'regionalisation' of the industry that has taken place in the last decades. This is clearly exemplified by the relocation of manufacturing by US and European firms to the so-called 'integrated peripheries' of Mexico and Central and Eastern Europe (Jürgens and Krzywdzinski 2008; Pardi 2017). This aspect of the globalisation and regional integration of the auto industry is well-known, and it is quite undisputed that the process has been primarily driven by the search of lower labour costs. For a detailed discussion of the case of the South American auto industry, following the approach on the specificity of capital accumulation in this region developed in Chapter 10 of this book, see Fitzsimons and Starosta (2018) and Fitzsimons and Guevara (2023).

9 The debate over the determinations of ground-rent and the implications for the comprehension of the exchange of agrarian and mining commodities on the world market

Introduction

Like other sections of Marx's *Capital*, the one on ground-rent has been approached in the past in the most varied manners. At present, however, many contemporary readings do not seem aware of this diverse theoretical lineage and simply proceed as if there were no alternative views of the determinations of ground-rent; or, even worse, they often overlook the contributions which pioneered the same interpretation that they are putting forward or the debate surrounding them. Thus, they end up treating long-standing arguments as radically novel insights. Be that as it may, and whatever the reasons for these omissions in the current literature on ground-rent, the point is that contemporary contributions hardly do any justice to the rich history of Marxist thought on the subject.

Against this backdrop, in this chapter, we shall offer a critical reconstruction of the debates and controversies over four fundamental aspects of the Marxian explanation of ground-rent. On the one hand, we aim at drawing attention to the existence of alternative perspectives which are critical of the dominant view in the literature. On the other hand, we intend to bring to light some contributions which have remained mostly overlooked but which, we think, are of utmost relevance for the investigation of several concrete phenomena of present-day capitalist society. Overall, this review of the different *problematiques* associated with ground-rent will serve us to offer a consistent approach to its determinations in line with the methodological and substantive foundations of the Marxian critique of political economy that we have unfolded in the rest of this book. On these general grounds, in the final section, we focus on some more concrete ramifications of this discussion and illustrate their significance for the inquiry into the dynamics of contemporary capitalism.

Controversies over ground-rent and its source

Ground-rent appears as a mass of value which ends up in the hands of landowners exclusively by virtue of their ownership of land. As Adam Smith (1982, 67) already observed, to the extent that 'the landlords, like all other men, love to reap where they never sowed', it is evident that this mass of value must be a portion of the

total surplus value available in society. In this sense, one could wonder which specific part of surplus value constitutes the social substance which takes the form of ground-rent, i.e. who are the wage-workers whose objectified surplus labour is represented as the surplus value that landowners pocket in the form of ground-rent. A first group of scholars argue that, with the exception of simple monopoly rent, ground-rent is surplus value extracted *within* the respective branch of production (in these debates the focus has tended to be on *agrarian* production, although most of the arguments can be extrapolated to all the 'primary' sector). By contrast, other scholars maintain that, except for absolute rent, all forms of ground-rent have their substance in surplus value produced *outside* agrarian production.

The first of these views was initially developed by the Soviet orthodoxy in the context of the debate over the role of agrarian production in the 'socialist' industrialisation process. This orthodox stance was fundamentally concerned with calling into question what it considered to be the 'conventional wisdom' among Russian Marxists, which had found in Preobrazhenski's (2022, 259ff.) contribution the most authoritative voice. According to this latter perspective, as any other surplus profit, ground-rent represented a transfer of surplus value from other branches of social production, which flowed into the agrarian sector through the sale of agrarian commodities at higher prices than their value. In contrast, the Soviet orthodoxy argued that, since value is a reified social relation, its magnitude can only be determined in the exchange process. Consequently, those authors rejected the notion that there could be such thing as intersectoral transfers of previously-constituted masses of value (Lyubimov 1930, 262ff.). In rather less sophisticated interventions in the debate, which eventually ossified as official doctrine, it was simply claimed that insofar as ground-rent originates due to the higher productivity of labour which produces in more favourable circumstances, the substance of surplus value that constitutes ground-rent must be found in that labour itself. This is the conclusion drawn by, for instance, Lapidus and Ostrovityanov (1929, 279): 'ground rent, which constitutes an extra profit over and above the average profit, is created by the higher productivity of the workers employed on better soil' (see also Economics Institute of the Academy of Sciences of the U.S.S.R. 1957, 222–23). Against this backdrop, even usually dissenting scholars like Vygodskiĭ (1974, 101) also claimed that 'from Marx's theory of rent it follows that both the absolute and the differential rent as well result from the labour of the agricultural worker'.

As Itoh (1988, 397n30) reports, this latter position disseminated in Japan after the translation of Lyubimov's book appeared in the 1930s through the work of Kōza-ha scholars, especially in the contribution of Yamada (1948; cited in Itoh 1988). Those first interventions triggered a long debate among Japanese Marxists. Although the initial critical reaction to Kōza-ha scholars was that of Rōnō-ha theorists (in particular, Sakisaka, 1930 and Susuki, 1952, cited in Itoh 1988), this alternative perspective gained international impact through its elaboration by the so-called 'Uno' school (Itoh 1980, 92; 1988, 240ff.; Sekine 1997, 75ff.; 2020, 657; Uno 1977, 98).

More recently, the arguments originally put forward by the Soviet orthodoxy resurfaced in the most varied contexts, albeit without acknowledgement of their intellectual lineage. At the level of abstraction of the simplest determinations of ground-rent, they can be found in the work of Murray (1977), and with a more elaborate grounding in the theory of value, in Indart (1990), Balardini (2017) and Foladori (2013). A similar stance has emerged within the controversy over the unequal exchange between countries, with a particular regional focus on Latin America (see, among others, Astarita 2010, 222–23; De Paula 2020, 353ff., 394ff.; Féliz 2021; Higginbotom 2016; Salvatore 1997). In this more recent spate of contributions, the essential train of thought of the old Soviet orthodoxy has been further complexified; for instance, through the consideration of agrarian labour of higher productive power as 'potentiated', or by approaching this branch of production subject to uncontrolled natural conditions as an instance of the 'modified' application of the law of value by virtue of those 'extraordinary circumstances'.

In our view, the first problem with this line of reasoning is that it stands in blatant contradiction with the Marxian explanation according to which an increase in the productivity of labour leads to a larger quantity of use-values produced in a certain time but leaves unaltered the total amount of value (Marx 1976, 130–31). Furthermore, as pointed out in our discussion of the nature and source of extra surplus value, the implication of the idea that ground-rent is constituted by the surplus labour extracted from agricultural labourers is that the total quantity of surplus value generated across society would no longer coincide with the total quantity of surplus labour performed by the working class as a whole. The immanent unity between materiality and social form characterising capitalist society would thereby be torn asunder.

For its part, the view which claims that the surplus value which constitutes ground-rent is the social representation of the surplus labour extracted from wage-workers from other branches of production can be tracked down to the works of Russian Marxists challenged by the Soviet orthodoxy, with the work of Preobrazhenski standing out among them. Yet this position saw greater elaboration and sophistication in the aforementioned interventions to the Japanese debate on the nature of ground-rent. In a nutshell, the main argument was that since in agriculture the market price is regulated by the least favourable conditions of production, those privately-performed fragments of social labour which set into motion a higher productivity are thus also expressed in that market price. And this leads to a quantitative divergence between the latter and the magnitude of value of agricultural commodities. As buyers of the consequently dearer agricultural produce mostly comprise members of the working class, the mass of value at stake entails a deduction of the surplus value that could otherwise be extracted from them should they need not consume those higher-priced commodities. It follows from this that the surplus value which constitutes ground-rent originates in those branches of production in which the said wage-workers/consumers are employed (i.e. exploited by capital). In the words of Itoh (1988, 242), 'we can be sure that the substance of the differential rent is to be regarded […] as a transfer of social surplus-labour through the social transactions of the commodity labour-power, wheat and payment of rent beneath the forms of value'.

A similar line of reasoning was also independently advanced in the 1970s in the context of the debates over dependency and the agrarian question in Latin America. The first wave of contributions to address the subject comprised the works of Spilimbergo (1974), Ferré (2007) and Laclau (1969). Thus, for instance, the latter author argued that 'differential rent […] is surplus value produced by the foreign worker which flows into the country [Argentina] by virtue of the ample demand for raw materials from the world market' (Laclau 1969, 294). The argument was later revisited and further developed with greater complexity and precision by Bartra (1979) and Margulis (1979), who addressed the question through the explicit consideration of differences between values and prices of production derived from the diverse organic compositions and turnover times of individual capitals. Among the other authors who also shared this perspective in those years, the following could be mentioned: Flichman (1977), Vergopoulos (1977), Gutelman (1974), Klimovsky (1979), Baptista (1980), Foladori (1984, 34–35; 1985, 96, who, as we have seen, subsequently changed his views) and Mommer (1986). More recently, with a similar focus on questions of dependency and uneven development on a world scale, this stance has been put forward by E. Arceo (2003), Iñigo Carrera (2017) and Anino and Mercatante (2009a). In international scholarship, concerning the simpler determinations of ground-rent, this theoretical position has appeared in the works of Mandel (1971, 280), Economakis (2010) and Fornäs (2013).

In our view, this latter perspective is the one which is consistent with the substantive and methodological foundations of the Marxian critique of political economy. As a matter of fact, it is in line with Marx's (1991, 799) own argument in his examination of ground-rent, where he characterises this part of surplus value as a 'false social value', which 'results from the law of market value to which agricultural products are subjected'.

The controversy around differential rent II

In his systematic-dialectical exposition of ground-rent as a concrete form of surplus value, Marx identified two types of differential rent. Both emerge as a result of differences in the productivity of labour which, in turn, derive from capital investments in natural environments with diverse material properties, fundamentally fertility or location. Differential rent I simply derive from the varying productivity of labour set into motion by capitals invested on plots of land with distinct degrees of fertility or proximity to consumer markets (Marx 1991, 799ff.). By contrast, albeit predicated on the existence of type I, differential rent II stems from the varying productivity of labour borne by successive capital investments on the same plot of land (812ff.). In both cases, the limit to the extensive or intensive application of capital is reached with the last investment that yields the average rate of profit (i.e. allows the normal valorisation of capital), given the market price for the respective commodity as determined by effective demand. Whilst the determinations of differential rent I have remained relatively uncontroversial among Marxists, those which underlie type II have been subject to contrasting interpretations, although this diversity of readings has hardly taken the form of an explicit debate.

What could be labelled the 'classic interpretation' of type II differential ground-rent can be traced as far back as the contributions of Kautsky (1988, 71ff.) and Lenin (1977, 116ff.; 1978, 304), and was subsequently continued in the Soviet tradition by Lapidus and Ostrovitianov (1929, 276ff.), and within Trotskyism by Mandel (1971, 276–78), just to name the most popular works. According to this reading, the surplus profits which constitute this form of ground-rent derive from the structure of capital investment in agriculture as a sequence of successive outlays which set into motion varying labour productivities, with those with a greater productivity than that which determines the respective market price yielding an extraordinary mass of social wealth which is pocketed by landowners. In the words of Kautsky (1988, 76), 'production cannot only be increased by bringing land under the plough, but also […] by advancing a larger amount of capital […] If this additional capital produces a higher yield when applied to good land than would have been obtained by using it to bring poorer land into cultivation, this additional yield constitutes a new surplus-profit, new ground-rent'.

Towards the end of the 1970s, this classic interpretation of differential rent II became explicitly challenged by two novel approaches, one of which would very soon turn into the new dominant view. The first one was pioneered by Michael Ball (1977), who took issue with the classical reading for relying on a 'marginalist' method for the calculation of the regulating price of agrarian commodities. Instead, he argued, the formation of the price of agrarian commodities must be obtained by means of an average between the different individual conditions of production. The second approach was independently developed around the same time by Guillermo Flichman (1977) and Ben Fine (1979). Insofar as this latter perspective eventually turned into the new hegemonic view, we shall concentrate our discussion on it and cast Ball's contribution aside.[1]

Flichman's (1977, 23) angle on the question takes as the basis for this type of rent the differences in the distribution of capital and access to loanable capital among agrarian capitalists due to the 'relative development of capitalism in agriculture'. According to this author, this situation 'allows more advanced capitalists to obtain extraordinary profits […] which when the renewal of tenancy agreements is due […] turn into ground-rent'. In a nutshell, in this approach, differential rent II is constituted by the landowners' appropriation of the surplus profits from technical innovation. For its part, Ben Fine's take is much more ambitious in terms of the attempt to remain closer to the theoretical legacy in the Marxian critique of political economy. His starting point is the critique of the classical interpretation for its allegedly neoclassical leanings (Fine 1979, 251). On these grounds, he then develops an interpretation which seeks to reconcile the idea of the regulation of agrarian prices by the 'average market value' with Marx's textual evidence on the impact of successive outlays of capital in agrarian production. His solution consists of an interpretation of the sequential nature of capital investment in agriculture as comprising different individual capitals of varying magnitudes. Thus, he conceives of capitals of a larger scale as consequently able to appropriate a surplus profit, which eventually turns into ground-rent. In Fine's own words, '[t]he significance for him [Marx] of unequal capitals is their unequal size as a source of productivity increase and surplus-profits' (251).

In our view, this interpretation of differential rent II is rather problematic for various reasons. First, to the extent that those surplus profits are thus conceived as only 'temporary', they negate the very meaning of ground-rent as a specific form of income (Ball 1980, 310). To put it differently, those profits correspond to what must 'genuinely' accrue to the valorisation of normal individual capitals rather than to landowners. Either way, in both Flichman's and Fine's interpretations the shared roots with type I of differential rent get out of sight. Second, in this reading the existence of differential rent II does not constitute a general determination of the distribution of surplus value but hangs on very specific historical conditions. Above all, it hinges on the separation of the personification of capital and landed property in two different individuals, since the extra surplus value would otherwise remain in the form of extraordinary profits for capital instead of being converted into ground-rent. On the other hand, the transformation of this form of surplus profit into ground-rent, albeit abstractly possible, depends on the extent to which it is generated by a technical innovation which becomes materially tied to the soil, so that it must remain there upon termination of the tenancy agreement. Third, as Iñigo Carrera (2017, 139–40) has critically pointed out in relation to Flichman, this conception of differential rent II implies that the average rate of profit which regulates the price of agrarian commodities is not determined by the productive conditions of *normal* agrarian capitals but through an average between the latter's rate of profit and that of *small* agrarian capitals (otherwise normal capitals could not obtain an extraordinary profit). Fourth, far from salvaging the 'concept of market value' from the inconsistencies of neoclassical economics, as Fine would have it, this interpretation deprives the market value of concrete determination, since it is ambiguously seen as determined by both the worst plot of land and the normal capital (Ball 1980, 311). Fifth, insofar as this approach concludes that this type of ground-rent derives from the comparatively larger investments of certain agrarian capitals, it begs the question of 'how it is possible for the same plot of land to have two different rental fees' (Iñigo Carrera 2017, 149). Worse still, this train of thought implies that capitals of a higher degree of concentration, and hence of greater economic power in their antagonistic relationship with landowners, actually pay higher rents than smaller, hence weaker, capitals (149). Lastly, specifically in the case of Fine, the textual evidence that he presents to substantiate the Marxian lineage of his reading is rather weak and taken out of context. As Ball (1980, 310) bluntly puts it, at most Fine's approach 'comes close to one out of fourteen cases considered by Marx'. Conversely, he quite simply ignores the numerous passages which contradict his interpretation.[2]

Despite all these shortcomings, this problematic interpretation disseminated surprisingly rapidly and widely, to the point of becoming the prevailing one among contemporary Marxists. Within the anglophone scholarship, the main channels for the spread of this approach have been the works by Fine (1979; 2013), Harvey (1982; 2006) and Fine and Saad-Filho (2003). Nowadays, this reading is broadly accepted and mostly referred to as the only perspective on this type of differential rent (e.g. Campbell 2002; Campling and Havice 2014; Munro 2012; Park 2014; Ramirez 2009; Vlachou 2002). Thus, it is increasingly rare to find works which trace back this position to the pioneering works from which it originated or which, at least, acknowledge that the interpretation of this form of differential ground-rent has been subject to an intellectual dispute (e.g. Haila 1990; Jäger 2003). What is more, this interpretation has been assimilated even by authors who are critical of Marx's theory of ground-rent (Bryan 1990). For its part, Flichman's contribution has had an analogous reception in the Spanish-speaking world. Initially, it was enthusiastically endorsed by a few authors (Kamppeter 1983; Margulis 1979) and critically rejected by others (Klimovsky 1985). But only few years passed before it started to be taken for granted as the only existing interpretation, in some cases with due acknowledgement of Flichman's original contribution (N. Arceo and Rodríguez 2006; Kabat 1999), whilst in others with no reference to its intellectual lineage (Anino and Mercatante 2009b; Astarita 2010; Balsa 2006; Farina 2006; Sartelli et al. 2008).

In opposition to this contemporary neglect of what we have termed the 'classical interpretation', and despite the undeniable room and need for its further theoretical elaboration, we do not think that there are solid substantive grounds for rejecting the fundamentals of that forgotten alternative view. In fact, as we shall argue in the last section, we think that such a stance on differential rent II is on the right track to comprehend various aspects of the intensive application of capital in agriculture from the point of view of the critique of political economy.

Controversies over absolute monopoly rent

Landed property over differential natural conditions is not the only basis for the emergence of ground-rent. In effect, although a certain plot of land may not allow to set into motion a higher productivity of labour, it still remains a limited condition of production and, therefore, that is 'in no way a reason for the landlord to lease out his land to the farmer for nothing' (Marx 1991, 884). Riding on the power granted by their legal ownership of land, landowners can withdraw their 'land from cultivation until economic conditions permit a valorization of it that yields him a surplus' (891) and, on that basis, exact payment of *absolute monopoly rent* for the use of their privately-owned plots of land. This elevates the market price of agrarian commodities over the price of production corresponding to the worst or marginal natural conditions. Three main problematic issues concerning this form of ground-rent can be discerned in the Marxist readings of this phenomenon.

The first one is the confusion between (and/or conflation of) two different forms of rent which originate in the active exercise of the absolute monopoly over access to this fundamental condition of production. On the one hand, there is the absolute monopoly rent which derives from the form taken by the process of formation of the general rate of profit in branches of production in which there are natural conditions that can be subject to exclusionary proprietary rights. In the rest of the branches of the social division of labour, this process entails the elimination of the difference between value and price of production through cross-branch capital mobility in search of a higher profitability. However, to the extent that in the primary sector landowners can erect barriers to entry for capital, they can capture as ground-rent the surplus profits produced by the existence of values that remain over and above the respective prices of production. Marx (1991, 895) calls this kind of social wealth pocketed by landowners *absolute rent*. A different type of absolute monopoly rent can emerge in circumstances where the sheer activation of the power of private ownership of land manages to raise the market price of agrarian commodities above its value. In this latter case, landowners capture ground-rent purely by virtue of the existence of a 'genuine monopoly price' (898). For this reason, we can refer to this mass of social wealth as *simple monopoly rent*. As should be evident, this kind of rent can also arise in situations where the corresponding price of production is higher than the magnitude of value. In this latter case, simple monopoly rent emerges from the difference between the market price and the price of production.

Most critiques of this Marxian explanation of absolute monopoly ground-rents have called into question the argument on absolute rent by throwing into relief the determination of all absolute monopoly rents by market conditions. Achille Loria's (1895, 492) pioneering critique captures very well the essence of all these objections: 'in any case', this author states, 'absolute rent cannot be constricted to the Procrustean bed of the labour theory of value, but obeys instead the more elastic discipline of monopoly income'. This train of thought reappeared a few years later in Diehl's (1899, 466) contribution, who adds that Marx's account of absolute rent is not only a logically irrelevant explanation but also 'historically and statistically' unverifiable. Along the same lines, Kautsky (1988, 78) objected to Rodbertus that '[i]t is very doubtful whether intensive agriculture could be practised with a lower than average composition of capital', and then further posited that according to Marx absolute rent is solely determined as 'a function of the extent to which the laws of competition still operate within the limits imposed by monopoly' (80). Lastly, mention must be made of Bortkiewicz's (1910, 217) early well-known critique, which quite simply comes down to the admission of his own inability to understand Marx's argument: 'Why should the difference between "value" and "price of production" provide a measure of absolute rent? […] Why does landed property only reach this precise point?'. Subsequent critiques roughly repeated Bortkiewicz's arguments (Amin 2014, 12ff.; Bartra 1979, 103; Blaug 1985, 286; Emmanuel 1972, 216ff.; Flichman 1977, 34; Margulis 1979, 80; Vergopoulos 1977, 81).

The response by Marxists to these objections essentially revolved around the reassertion of Marx's own distinction between absolute rent and simple monopoly rent. The first author to draw attention to the difference between those two types of rent was probably Harvey (1988, 181–82) in his reply to Emmanuel's (1972, 216ff.) critique. About the same time, an identical line of response to Marx's critics can be found in the works of Clarke and Ginsburg (1976), Fine (1979) and Ball (1980), although, in Fine's case, he considers that the difference between values and prices which lies at the basis of absolute rent is determined by differential rent II. Despite these defences of Marx's original arguments and their explicit acknowledgement of the distinction between absolute rent and simple monopoly rent, a great deal of the more recent discussion still revolves around the classical objections (Economakis 2003; 2006; Evans 1991; 1999a; 1999b; Sandemose 2006).

The second issue to note concerning the reception of the Marxian exposition of absolute monopoly rent is the virtually total omission of the question of the qualitative and quantitative imbrication of this form of ground-rent and differential rent. The prevailing position is that the magnitude of absolute monopoly rents has no relationship whatsoever with the differences in the natural properties of the soil (Lapidus and Ostrovitianov 1929, 283). This is all the more noteworthy insofar as Marx was quite explicit that although in their simplest determination, absolute monopoly rents correspond to the worst conditions of production, their effects extend differentially to all lands and capital investments. Thus, he states, 'if the price of the product from a unit area of the worst land = P + r, all the differential rents rise by corresponding multiples of r, since by our assumption P + r becomes the governing market price' (Marx 1991, 897). In other words, at stake here is a differential appropriation of absolute monopoly rents. Among the few exceptional cases of authors who did throw into relief this phenomenon, mention must be made of Kautsky (1988, 80) and Bartra (1979, 72–73). More recently, Iñigo Carrera (2017, 58–60) brought this determination to light, also adding that if absolute monopoly rents are not an ephemeral effect of short-term conjunctural market circumstances, they tend to turn into differential rents. The reason for this is that the persistence of exceptionally-high market prices as a result of the exercise of the absolute monopoly power of landowners can incentivise production in formerly unutilised lands or intensive disbursement of formerly unprofitable capital investments, which come to be determined as those which regulate the price of production.

This leads us to a final aspect of debates around absolute monopoly rent. Usually, the latter has been treated as resulting from the intentional action of landowners, whereas differential rent is generally depicted as a result of the pure 'automatism' of economic determinations. As a matter of fact, one implication of Fine's (1979, 269–70) response to the classical critique by Bortkiewicz (1910), was to reassert the economic determination of absolute rent, which implicitly left simple monopoly rent deprived of objective determination. However, as Iñigo Carrera (2017, 47–54) observes, the latter can also emerge as a result of a purely 'economic' movement. For instance, that would be the case where the solvent social need for a certain primary commodity outstrips all possible output from available lands and if there were no possibilities for ramping up production through additional capital investment (as would be the case in a sector unconstrained by non-reproducible natural conditions). As we shall see in our discussion of the oil sector in the last section, even when ground-rent emerges from the active exercise of the landowner's absolute monopoly power, this conscious and voluntary action still remains a mediating form of concrete economic determinations.

Further issues in the investigation of the peculiarities of the primary sector: the problem of the 'personification of economic categories'[3]

Although it does not constitute, properly speaking, a debate or controversy, there is a last relevant issue worthy of discussion: the problem of the 'personification of economic categories' (Marx 1976, 92) in the primary sector. More specifically, this question refers to the existence of certain social subjects in primary production that cannot be directly and clearly classified as members of neither of the 'three great classes of modern society based on the capitalist mode of production' (Marx 1991, p, 1025), i.e. wage-labourers, capitalists and landowners. In the Marxian tradition, this problem can be traced back to the classic 'Agrarian Question', and particularly to the discussion on 'peasants', which were seen as social subjects that differ from those that should express the full development of the capitalist mode of production (Kautsky 1988; Lenin 1964). In more recent times, following the pioneering work of Gibbon and Neocosmos (1985) and Bernstein (1988), this notion has been progressively left behind. Instead, these authors consider that the peasant must be grasped through the specifically-capitalist category of 'petty commodity producer'. However, rather than systematically unfolding the determinations of the process of capital accumulation that engender petty commodity production, they just point, by way of explanation, to a set of external circumstances, such as 'conditions of access to key resources', the configuration of 'markets', 'nature' and 'government policies', among others (Bernstein 1994, 56). In other words, according to this approach, the limits and potentialities of petty commodity production cannot be immanently derived from the general determinations of the 'laws of movement of capital'.

Yet, we think that it is precisely through the systematic exposition of the general form-determinations of capital that one can shed light on the determinations of social subjects in primary production. As we have argued in previous chapters of this book, in its general determination as self-valorising value, capital is actually a materialised social relation between commodity owners differentiated into social classes, which, in its fully-developed form as the total social capital, becomes inverted into the alienated subject of the unity of the process of social reproduction and its expansion (Postone 1993; Starosta 2016). From this standpoint, every privately-organised productive unit, as a materially integral part of the social division of labour, becomes necessarily subsumed under the movement of formation of the general rate of profit. It follows from this that, whether they have the phenomenal form of an individual capital or not, all productive units become formally determined as if they were one. Hence, the human individuals whose reproduction process is subsumed to that private fragment of social labour, become invested as personifications of capital, labour-power and, eventually, landed property. Seen in this light, the peasant is an individual who is simply characterised by the concentration in their own subjectivity of the personification of those three different and antagonistic social roles (Marx 1988, 556; 1994, 142).

This approach to the social determinations of the peasant reframes the discussion of the characterisation and historical potentialities of the peasantry in relation to the kind of capital they personify and the relation that they have in that capacity with landed property. As already discussed in Chapter 8, it was precisely when considering peasant agricultural production that Marx hinted at the basic elements for a systematic exposition of the specificity of small capitals and their respective form of valorisation. In a nutshell, in those pages, Marx implies that despite its significantly smaller scale, the individual capital which the peasant personifies can survive competition from normal capitals. This is possible because ‘the smallholding peasant’s exploitation is not limited by the average profit on capital, in as much as he is a small capitalist; nor by the need for rent, in as much as he is a landowner’ (Marx 1991, 941). Therefore, the smallholding’s higher costs could be offset by having ‘the absolute limit’ to its reproduction in ‘the wage that he pays himself, after deducting his actual expenses’ (941–42). In other words, this absolute limit implies the absence of all profitability as personification of capital and an income which boils down to the peasant’s condition as personification of labour. Nevertheless, before reaching this extreme limit, the small agrarian capital does yield positive profitability, which is regulated by the rate of interest on the liquidation value of productive assets. Against this backdrop, the limit selling price which secures the small capital’s reproduction could even stand below that of the regulating price of production of normal capitals. Under those circumstances, the peasant’s small capital would outcompete normal capitals, with the result that a portion of the surplus labour performed there would be ‘presented to society for nothing’ (942).

The ‘colonisation’ of agrarian production by small capitals leads to a particular relationship between capital and landed property. In principle, there should be a tendency for the repulsion and separation between them. The reason for this is that capital invested in the acquisition of land yields the rate of interest only (Marx 1991, 760–61), whilst its valorisation in production yields the average rate of profit, which is, by definition, normally higher (480–82). By contrast, by virtue of the significantly lower-than-average rate which regulates the valorisation of small capitals, they are unaffected by this barrier to land ownership; it is a matter of indifference to them whether to invest additional capital in buying land or in the expansion of the scale of production. Hence the observable empirical tendency in agriculture for a tenancy regime which fuses together capital and landed property.

A formally analogous situation arises in the oil industry, where landed property has been often imbricated with industrial capital. Perhaps the clearest expression of this phenomenon is to be found in the ‘oil states’ of the Organization of the Petroleum Exporting Countries (OPEC), where nationalisations led to the exploitation of oil reserves by state-owned enterprises. In these countries, nation-states have conjoined the social role of both landowner and capitalist. Nevertheless, as we shall see in more detail later, this joint personification of different ‘economic categories’ in the oil industry can also be observed in cases where the property of land and of capital is formally differentiated, as in the United States throughout its history and in OPEC countries prior to the nationalisations of the 1970s.

Now, it is clear that in the case of the oil industry, this joint personification of landed property and capital cannot have the same roots as in the agrarian sector, since capital invested in the former is highly concentrated. How can one explain, then, this phenomenon? We think that in this case, the joint personification arises directly from the peculiar material features of the kind of ‘land’ involved in the extraction of oil. First, the oil industry differs from agriculture by the non-renewable nature of extractive resources in general. This has the self-evident but fundamental implication that upon completion of each production cycle, the land returns to the landowner in an inevitably deteriorated shape. In the second place, ownership of hydrocarbon deposits can be separated from ownership of land itself. In most oil-producing countries this separation of landed property has a clearly tangible legal expression, since all subsoil resources are considered state property, irrespective of the property relations over the surface. But even in the United States, where the ownership of the surface includes the rights to underground resources, access to oil deposits can be negotiated independently of the use of the land itself (Brown et al. 2016, 24). Lastly, a third peculiarity of extractive industries is that the actual availability of the resource as a means of production requires the previous advance of significant magnitudes of capital in exploration.

The crucial point in this regard is that these characteristic features have historically led to a situation where oil companies have a *de facto* control of reserves, even without being formal owners of oil fields. US oil leases provide a good illustration of this tendency, since in this country the property of the oil fields appears clearly differentiated from industrial capital. In this sense, the key aspect of leases is the ‘held-by-production’ clause. By this provision, the lessee is allowed to extend the duration of the contract beyond the original term, as long as oil is being produced (J. Smith 2018). Therefore, oil-producing capitals become, in practical terms, owners of the oil, since the landowner cannot reclaim the possession of the resource until its depletion (or until extraction becomes unprofitable). In this sense, the formal landowner is restricted to the personification of superficial landed property, and the lessee obtains the factual ownership of the subsoil’s resources.

From the standpoint of the owner of the superficial land, there is actually a sound reason to accept this form of long-term lease that implies a practical transfer of the property over oil to the lessee, that is, to oil capital. In effect, as already mentioned, the landowner of oil fields cannot expect to recover the land in the same original conditions that it had at the time of the lease. In this sense, landowners usually demand an upfront payment (the so-called ‘bonus’) to lease their oil fields, which varies for each lease according to the expected quality and magnitude of the field, in addition to the customary and relatively fixed royalty payments across fields. Actually, the fact that the bonus varies across fields means that it would have to be equal to the ‘present value’ of the future rent to be obtained from the exploitation of the oil field (Davidson 1963, 104; McKie and McDonald 1962, 108). Now, as agreed among the different schools of economic thought, the capitalisation of future rent constitutes the determination of the price of land. In Marx’s (1991, 944) words, this price ‘is nothing but the capitalized and thus anticipated rent’. Thus, if the leases involve an upfront payment that allows the lessee to obtain a future rent from the extraction of oil until the depletion of the field, this means that oil capital has essentially bought the resource, and with it, the right to appropriate the rent.[4]

In sum, although for reasons entirely different than in agriculture, in the oil sector, we also find a strong tendency for the combination of the social roles of landowner and capitalist in the same social subject; in this case, the ‘oil company’. It must be stressed, however, that here we are not focusing on the juridical aspect of the matter, i.e. on the question of the *legal ownership* of the natural resource. Rather, this conclusion applies to the question of the *personification* of the social role of landowner as the subject with the capacity to appropriate social wealth in the form of ground-rent. We shall return to this in the following section.

Some implications for the analysis of contemporary capitalism

In this last section, we would like to address some implications of themes discussed so far in the chapter which should illustrate their relevance for the comprehension of concrete phenomena of contemporary capitalism.

The controversy over the source of surplus value which constitutes ground-rent is of decisive importance to understand the role of raw material-exporting countries in the world market. In effect, as we shall see in greater detail in Chapter 10, the conclusion that ground-rent is surplus value extracted outside agrarian production implies that raw material exporting countries experience a permanent *inflow* of extraordinary social wealth which originates in the respective consumer countries. In other words, as much as within a national sphere of circulation the exchange of ground-rent-bearing commodities involves a transfer of surplus value produced by the working class as a whole towards the agrarian sector, an analogous process takes place at the level of the world market, albeit from raw material importing countries towards the respective exporters.

This conclusion openly contradicts all explanations of the specificity of the latter type of national process of accumulation based on analyses that posit the existence of a flow of surplus value in an inverse direction, that is, on the existence of an outflow of surplus value towards other countries, more specifically, towards those (mis-)termed ‘developed’, ‘core’ or ‘imperialist’ (for example, Dussel 2001; Emmanuel 1972; Marini 2022). In effect, what would have to be expected in a country toward which there permanently flows an extraordinary mass of social wealth from abroad is a multiplied potential for the development of its national process of capital accumulation. Yet, what these countries normally present is a situation of recurrent crises, a permanently lower productivity of labour, low wages, an unusually large and historically growing surplus population and so on.

Our solution to what might appear at first sight as paradoxical is to examine how the release of surplus value to the raw material-producing countries on the part of global total social capital transforms into its opposite, that is, into the *recovery* of this surplus value. In this sense, we shall argue in Chapter 10 that the specificity of most Latin American national processes of capital accumulation (and actually all South American ones) does not simply consist of being a source of cheap raw materials and means of subsistence for the world market. Specifically, those territories are also determined as sources for the recuperation of ground-rent by the global total social capital. In turn, we shall see that this latter potentiality is realised in a whole series of concrete forms which, given their nature, generate the existence of a specific limit to the expansion of the process of capital accumulation in this type of countries. This is consistent with the conditions of increasing impoverishment normally evident therein.

The implications of the controversy over differential rent II are not as wide-ranging, yet they are far from lacking in relevance. As a matter of fact, the intensive investment of agrarian capital has been a recurring theme in debates on the nature of the agrarian sector in Latin America, particularly in connection with the apparent limits to capitalist development in those societies (de Janvry 1981; Kay 2010; among others). Thus, in the 1960s most sectoral analyses agreed that the main problem in agrarian production resided in the low intensity of capital investment (CEPAL 1959; CIDA 1965). In turn, many scholars pointed to this phenomenon as the cause of the inability of Latin America to embark on a sustainable developmental trajectory, insofar as the latter hinged on the availability of foreign currency in the central bank which was mostly provided by agrarian exports (Vitelli 1999). By contrast, since the 1980s and especially during the 1990s, a new wave of sectoral analyses emerged which stressed that a substantial transformation in the patterns of agrarian investment had taken place. In this novel scenario, these scholars argued, there was a greater scale and pace of technical innovation in Latin American agriculture (Obschatko et al. 1984; Pucciarelli 1997). The old picture of the 'absentee feudal landlord' (Ferrer 2004; Giberti 1962) was left behind and was replaced with the image of a dynamic 'Schumpeterian entrepreneur' as the eminent social subject of agrarian production (Bisang et al. 2008). However, little light was shed by these literatures on the underlying economic foundations of those seemingly radical mutations of agriculture in Latin America.

The Marxian explanation of differential rent II can certainly contribute to laying bare the main determinations at stake in these recent changes in the configuration and dynamics of the agrarian sector. However, the different readings of the respective sections of *Capital* that we reviewed earlier lead to starkly contrasting views of the determinants of the intensive application of capital in agriculture. According to the currently hegemonic perspective, a low intensity of capital investment must be explained through the power of landowners to appropriate the potential surplus profits which emerge upon a subsequent round of capital investment on the same land. Conversely, a high intensity of capital investment must be accounted for by the possibility that the agrarian capitalist captures those surplus profits. By contrast, according to the classical interpretation, a lower intensity of application of capital obtains when the respective market price of agricultural produce drops to a correspondingly low level, which prevents the last investment of capital from yielding the normal rate of profit. Conversely, a high intensity of capital investment obtains when market prices rise to allow subsequent outlays on the same land to reach normal profitability.

Against the backdrop of our critical discussion of the controversies over differential rent II, it seems to us that it should be evident that the explanation of this recent pattern of greater capital intensity in Latin American agriculture must be searched in the evolution of the price of agrarian commodities. Indeed, this is the argument forcefully put forward by Iñigo Carrera (1999; 2007, 101ff.; 2017, 325ff.), who convincingly shows the link between the fluctuations in the intensity of capital investment in Argentine agriculture and the effects of the mechanisms of recuperation of ground-rent by the global total social capital on the level of domestic agrarian prices. A thorough discussion of this issue exceeds the scope of this chapter, so we refer readers to Iñigo Carrera's works just cited for a more in-depth treatment of the subject.

The last two controversies reviewed above, i.e. those related to absolute monopoly rent and to the joint personification of the social roles of landowner and capitalist, allow us to address some further ramifications of the particular stance adopted concerning the different determinations of ground-rent that have been at the heart of those Marxist debates. More specifically, these relate to the peculiarity of extractive industries in contrast to the 'classic' agrarian case. In what follows, we shall approach this issue by focusing on the oil industry.

First and foremost, it is apparent the prominence of direct actions in the establishment of prices in the oil sector, in contrast to the more immediate market determination of agrarian prices. Thus, the 'oil crisis' of 1973–1974 placed the nature of the profits derived from the sharp increase in world market prices in those years at the centre of academic disputes. However, in light of our previous discussion of absolute monopoly rent, we think that Marxist analyses of this issue suffer from serious limitations. Indeed, a first position directly denies the very existence of any type of rent beyond differential ones in the oil industry. On the one hand, the possibility for the emergence of absolute rent is ruled out on the grounds that the organic composition of capital in this industry is above average (Bina 2013, 120; Nwoke 1984, 52). However, hardly any evidence is provided to substantiate this point. On the other hand, simple monopoly rent is discarded through the rejection of 'Monopoly Capital' theory (Bina 2013, 41). Now, although in more general terms we concur with the critique of 'Monopoly Capital' theory, its extension into the critique of the notion of 'simple monopoly rent' completely misses the point. For it should be clear that this type of rent has nothing to do with the monopoly over *capital*. Instead, the issue at stake is the monopoly over *scarce and/or non-reproducible natural conditions of production*. This same confusion is also present in other authors who make the opposite case that simple monopoly rents do exist in the oil industry. For instance, Chevalier (1976, 285) states that 'monopoly rents' arise from high 'barriers to entry', which, however, he does not see as generated by *landed property*.

By contrast, Massarrat (1980, 31–32) correctly states that absolute monopoly rents are rooted in the monopoly over land, even though he does not clearly differentiate between absolute rent and simple monopoly rent. However, this author conceives of absolute monopoly rents as only relevant to the worst conditions of production, and thus separates them off from differential rents. In this manner, absolute monopoly rents lose virtually all significance for the analysis of the oil industry. In addition, Massarrat postulates that the worst conditions of production that regulate the market price of oil are actually those of coal production, since he sees both oil and coal as essentially the same 'commodity': energy (34). This also leads to hide absolute monopoly rents further from view in his analysis, since every oil field is rendered better than the marginal conditions of production of 'energy', namely, coal mines. In fact, this same line of reasoning has led Werrebrouk (1979, 126) explicitly to conclude that oil rent is exclusively formed by differential rents.

In a nutshell, the common thread that ties all these Marxist analyses of the oil industry together is the dismissal of the relevance of the absolute monopoly over land in the determination of the magnitude of oil rent, thus neglecting the role of direct and conscious actions as necessary forms of realisation (i.e. mediating concrete forms) for the establishment of oil prices. In this sense, Bina's (2013, 87) conclusion on the role of OPEC in the oil industry is quite telling: 'if tomorrow OPEC closes its doors for good and the members were to depart and go about their business, commensurate with the productivity of their oil, they would earn the same'.

Yet, we think that our approach to absolute monopoly rents allows us to explain the striking significance of direct power relations in the oil industry on the very grounds of the Marxian critique of political economy. Take, for instance, the stage often characterised by the domination of the 'International Petroleum Cartel' over global oil markets (lasting from the late 1920s to the oil crisis of the 1970s). In those decades, a reduced group of seven large North American and European oil companies (the so-called 'Seven Sisters') were able to regulate production through a system of quotas and thus influence oil prices, limiting their downfall tendency despite the continuous incorporation of the more 'productive' oil fields of the Middle East (*vis-à-vis* the formerly predominant US fields). This means that oil firms were restricting production (and therefore limiting the investment of capital) in order to raise oil prices. To put it simply, they were acting as landowners. In this way, the 'International Petroleum Cartel' managed to maintain the profitability of US oil fields (which were the 'worst' lands for oil production), whilst, simultaneously, they multiplied differential oil rents in the Middle East and other oil-producing countries with better than average natural conditions for oil extraction. Thus, in this scenario, even differential rents did not automatically result from 'pure' market forces. Quite the opposite, they arose as a consequence of the active exertion of the absolute monopoly over land that kept the worst oil fields in production. In other words, direct regulation of output on the part of the oil cartel increased total oil rent compared to the level that this rent would have attained otherwise.

Still, it must be stressed that this does not imply the abstract negation of the essentially indirect form of the capitalist social form of regulation of material production. On the contrary, the direct and conscious regulation of prices by the 'International Petroleum Cartel' (and a similar argument could be made about the OPEC after the oil crisis) was a normal concrete form of realisation of the Marxian 'law of value', given the peculiarities of the oil industry and, specifically, the non-renewable character of oil. In effect, oil landowners have a greater capacity to restrict the use of the natural resource that they monopolise *vis-à-vis* agrarian ones. The reason for this is that, unlike the case of agrarian landowners, they can fully or partially withdraw from production the land they own without incurring in an irrecoverable loss of output, which is the material bearer of their ground-rent. To put it differently, the ground-rent which they do not appropriate within the current productive cycle can, *ceteris paribus*, still be captured in the following periods (Iñigo Carrera 2017, 50). On this basis, the direct regulation of production by landowners, although it may initially manifest in the form of the emergence of simple monopoly rents, ends up turning into differential rent (insofar as it allows the incorporation of lands which, without the mediation of such a conscious and voluntary action, would not even yield the normal rate of profit). This constitutes a good example of the previously discussed imbrication between differential and absolute monopoly rents, and also illustrates how non-economic social forms can mediate the quantitative determination of ground-rent.

The difference between the agrarian and oil sectors ultimately resides in the fact that the latter's absolute limit to the availability of the natural resource *vis-à-vis* the solvent demand for it is expressed in a definite timeframe for the process of depletion. In this sense, the direct action of landowners that mediates the generation of simple monopoly rents is grounded in the economic necessity to regulate current output with regard to both the present and future relationship between available reserves and the demand for them. The *economic content* of the exercise of monopoly power – i.e. the regulation of the rhythm of extraction and of the geographical organisation of production – took *concrete institutional form* through the constitution of a new 'cartel' comprised by oil exporting countries during the 1970s. As Delgado Wise (1999, 26–27) observes, the rise of prices caused by the actions of OPEC largely was an expression of the need to recompose the relationship between output and reserves, which had significantly deteriorated. At the same time, it was also meant to incentivise production in novel areas with higher costs, like Alaska and the North Sea.

This argument about the material determination of the action of the 'International Oil Cartel' evidently links up with our discussion of the joint personification of landed property and capital in the oil industry.[5] In a nutshell, our argument in this regard is that the 'Seven Sisters' played, besides their obvious role as industrial capitals, the practical personification of landed property. In effect, these firms had secured effective control over the world's best oil reservoirs through the leases obtained in the first decades of the 20th century, despite oil states having remained the legal owners of both the soil and the subsoil (Yergin 2009, 504, 523). This is far from a semantic discussion. Indeed, the point precisely is that it is only because those contracts gave capitalist firms the monopoly *over land* that we can explain their power over oil prices without either resorting to 'Monopoly Capital' theory or, worse still, simply explaining away the oil cartel by deeming all forms of 'price administration' as pre-capitalist traits, as Bina (2006, 8–16; 2013, 91–92) and Masarrat (1980, 40–41) do. The peculiar form taken by their role as joint personifications meant that multinational oil companies (and not the oil states as the formal owners of the lands) were the social subjects whose intentional actions had to mediate the 'social compulsion' to maximise the appropriation of a portion of the surplus profit in the form of oil rent. In this sense, it is suggestive that, when in the 1970s oil states reclaimed full ownership of the land, they did not simply re-negotiate the terms of the leasing contracts. They moved forward to nationalise oil firms, and thus reproduced the joint personification of landed property and oil capital, but now in the novel figure of the state-owned oil company. This seems another strong piece of evidence that the exertion of the monopoly over land in the oil industry tends to be fused together with the personification of industrial capital.

Conclusion

In this chapter, we have offered a critical overview of the main controversies and debates over the determinations of ground-rent which have taken place among Marxists since the publication of Marx's *Capital*. In all cases, we have also advanced our own stance on each of these questions, with a view to articulating a general unified perspective on those diverse phenomena which pertain to the workings of the 'law of value' in those branches of social production in which the labour process is subject to natural conditions which lie beyond the normal control by capital, i.e. without affecting its valorisation at the general rate of profit. After presenting our views on the source of surplus value that constitutes ground-rent, differential rent II, absolute monopoly rents and the question of the joint personification of capital and landed property, we also offered some brief illustrations of their implications and ramifications for concrete empirical research. In this way, we sought to bring to light the significance of the investigation of those more abstract determinations for the critical inquiry into contemporary capitalism.

Notes

1 For an extensive and detailed discussion of Ball's approach, see Caligaris and Pérez Trento (2017).
2 See Starosta and Caligaris (2017, 336–38).
3 The following section draws partly on Caligaris et al. (2022).
4 The fact that the upfront bonus is complemented by a royalty payment appears to be explained by the uncertain results of the exploration phase, since this arrangement allows landowners and capitalists to share the risks involved (Davidson 1963, 104).
5 For reasons of space, we could not include the agricultural sector in this discussion. See, however, Caligaris et al. (2022).

10 The specificity of capital accumulation in Latin America

A critique of dependency theory

Introduction

In his overview of theories of imperialism, unequal exchange and dependency, Dussel (2001, 205–14) perceptively notes that most Latin American attempts to account for the phenomenon of global uneven development and its specific manifestation in this part of the globe, whether debates on the mode of production prevailing in (or since) colonial times (Assadourian et al. 1973; Gunder Frank 1969; Laclau 1971) or sociological critiques of mainstream development theories (Bambirra 1978; Cardoso and Faletto 1979; Dos Santos 1978), have ultimately failed to go beyond explanations that focus on the historical genesis of the '*differentia specifica*' of the region. Or, at most, they simply provide descriptions of the outward 'empirical appearances' of the mechanisms that reproduce the limited potentialities of capitalist development in these countries, without inquiring into its *fundamental determinants*. In other words, Dussel's (2001, 211) argument goes, those approaches choose to follow a 'phenomenal road' in which 'not a single one of the essential categories of Marx's critical political economic discourse is used'. By contrast, he claims, the critical-scientific explanation of the qualitative specificity of Latin American societies must be based on a methodologically rigorous systematic development of the form-determinations that shape the unfolding of the law of value on a global scale (209).

Among the few notable exceptions that do follow this latter road, Dussel mentions Ruy Mauro Marini's (2022) pioneering and influential *Dialectics of Dependency*, based on the essentiality of 'super-exploitation' of labour as the distinguishing mark of Latin American national societies, and Kalmanovitz's (1983) critique of dependency theory. Moreover, in *Towards an Unknown Marx* Dussel (2001, 207–9) himself puts forward his own idiosyncratic take on unequal exchange based on differences in the organic compositions of capital in the 'centre' and 'periphery' (an approach that he traces back to non-Latin American scholars such as Grossmann, Battleheim and Palloix). Indeed, it seems fair to conclude that Marini's and Dussel's works probably are not only two of the most widespread Marxist approaches to dependency theory but also, without a doubt, the most sophisticated and rigorous theoretical perspectives when it comes to the attempt

DOI: 10.4324/9781003201939-11

to marry that Latin American intellectual tradition and the Marxian critique of political economy.

The purpose of this chapter is thus critically to examine both Marini's and Dussel's approaches to the study of the social determinations and developmental potentialities of Latin American societies. We argue that there are two main weaknesses in all versions of dependency theory, which these Marxist reformulations fail to overcome, and which underlie their inability to offer a critical understanding of the fundamental determinations of uneven development on a world scale and its particular expressions in Latin America. In the first place, despite their self-conscious effort to transcend the 'methodological nationalism' characterising mainstream development studies, they nonetheless fail firmly to ground the constitution of national or regional specificities in the essentially global dynamics of the capital accumulation process. Secondly, and relatedly, they more or less explicitly end up conceiving of political forms of capitalist social relations, i.e. class struggle and/or the state (and its policies) as somehow autonomous from the (alienated) economic content of this historically-specific mode of existence of the human life process: the self-movement of valorisation of value. In brief, dependency theory is unable to uncover the inner connection between what outwardly appear as two sets of differentiated aspects of capitalist production which, constitute, respectively, their content and necessary mode of existence: the economic and the political, and the global and the national. By contrast, we shall submit that the key question resides in comprehending that the production of surplus value is an attribute of the *global total social capital*, whose *immanent unity or content* obtains at the level of the *world market*, but which becomes *self-differentiated* into qualitatively specific *national forms* that constitute individual organs of the international division of labour of uneven developmental potentialities.

Ruy Mauro Marini's and Enrique Dussel's attempts to marry dependency theory and the Marxian critique of political economy[1]

Ruy Mauro Marini's dialectics of dependency

Ruy Mauro Marini is probably the most influential author from the Marxist dependency theory tradition. His contribution stands out for making *super-exploitation* (hereafter SE), the fundamental or essential determination that marks the specificity of so-called 'dependent economies'. This feature, his argument goes, crystallises primarily as a *nationally-embedded* method of production of surplus value, which emerges as an 'adaptation mechanism' through which peripheral economies react to the outflows of surplus value that result from the 'unequal exchange' relations that they establish in international circulation with advanced capitalist countries (Marini 1978, 62ff.; 2022, 130ff.). In turn, this inequality in the world market results from the fact that certain countries (from the so-called 'centre' in dependency theory's jargon) produce certain commodities which others (from the so-called 'periphery') are unable to produce. Alternatively, the unequal exchange is also said to result from the centre's relatively higher productivity of labour for the same commodities, which leads to them reaping surplus profits (Marini 2022, 127–28). Either way, these conditions allow industrial countries to ‘evade the law of value’, that is, to sell ‘their products at higher prices than their value’, thus forcing ‘disadvantaged nations’ to ‘cede part of the value they produce’ (128).

The necessity of SE develops as a ‘compensatory mechanism’ in the face of these ‘value transfers’ (Marini 2022, 128).[2] Whether through the increase in the intensity of labour or the extension of the working day, the mass of value produced by workers goes up and, under the assumption of a given wage, so do the mass and rate of surplus value. A similar effect obtains by means of a sheer cut of the real wage, which also increases the amount of surplus value, albeit without augmenting the total mass of value produced. In all cases, and regardless of the concrete ways in which these different forms of SE become articulated, they involve the payment of labour-power below its value, whether by virtue of the curtailment of the consumption of use-values which are necessary for the *normal* reproduction of the ability to work of wage-labourers, or due to an abnormal daily expenditure of labour-power leading to its premature exhaustion (132). In Marini’s own words, SE essentially comprises the increase in surplus value through the conversion of ‘part of the wage fund into the fund for capital accumulation’ (161). Thus, this modality of surplus value extraction becomes the primordial determination of the specific form assumed by capitalist development in Latin America, insofar as ‘the three mechanisms identified – the intensification of work, the extension of the working day, and the expropriation of part of the labour necessary for the worker to replenish his labor power – give rise to a mode of production based exclusively on the greater exploitation of the worker, and not on the development of his productive capacity’ (131).[3]

Now, this configuration of the ‘mode of production’ engenders its specific ‘mode of circulation’. More concretely, the SE of labour-power tends to generate a disproportion between domestic production and consumption. To begin with, SE tends to reduce the wage-workers’ consumption, whether in absolute terms or in relation to total output. In this sense, Marini submits that in dependent economies the wage primordially acts as determinant of the rate of surplus value rather than as a source of solvent demand, as contrastingly happens, allegedly, in central economies. Domestic demand thereby depends to a larger extent on the amount of surplus value, which is specifically augmented by virtue of the existence of SE. However, a portion of surplus value escapes domestic accumulation and flows abroad via unequal exchange (especially during the so-called ‘agro-export’ stage), or through other forms of international value transfer which emerge and consolidate in later phases of capitalist development (such as profit remission and royalty payments).

Moreover, Marini points out that this exacerbated dependence on surplus value as a source for the realisation of the value of domestic output is further compounded by the relatively small share of domestic manufacturing in the overall supply of means of production, which implies that most of the surplus value spent within peripheral countries takes the form of revenue instead of being devoted to accumulation. This generates a peculiar structure of domestic consumption concentrated in 'luxury goods', which were initially provisioned by means of imports until the relative breakdown of foreign trade with the eruption of the 1930 crisis, and thereafter increasingly through domestic production as the subsequent turn to Import Substitution Industrialisation (ISI) gathered pace in Latin America. Thus, on the one hand, the size of domestic demand becomes specifically restricted by the dominantly export-oriented nature of local production and the drain of surplus value resulting from 'unequal exchange'; on the other, its composition becomes split into two clearly and strictly delimited spheres: a 'lower' segment corresponding to the individual or personal consumption of the working class, which is particularly limited by virtue of the existence of SE, and a thereby expanded 'higher' segment which relies on non-accumulated surplus value.

According to Marini, insofar as the relatively limited development of relative surplus value production still prevails in peripheral countries, this peculiar structure of the circulation of capital cannot but further bolster the tendency to increase the appropriation of surplus value by means of the SE of the working class which, in turn, leads to the continuous reproduction of their dependent status. Moreover, this necessitates permanent additions to the supply labour-power to sustain the SE of workers without undermining the reproduction of capital, which would otherwise risk clashing against a lack of 'human exploitable material' with the productive attributes demanded by the accumulation process itself. The 'circuit of dependent capital', Marini concludes, thereby consists of a peculiarly 'deformed' articulation between production and circulation. And he stresses that this unity between the two phases of the cycle of capital differs from the allegedly 'normal' and 'virtuous' combination prevailing in central countries, where working-class consumption acts as a vigorous source of effective demand for the realisation of capitalised surplus value.

Thus, as Barreda Marín submits in his meticulous reconstruction of both Marini's works and the subsequent debates to which it gave rise, if colonial forms of integration of Latin American countries into the world market and unequal exchange constitute the 'historical and functional determinants which lead to the *necessity* of SE', the large pool of latent relative surplus populations inherited from pre-capitalist societies, migratory flows and the 'dislocated' structure of the circuit of dependent capital, constitute the 'condition of possibility for the functioning of SE' (Barreda Marín 1994, 202), i.e. the *ossification* of capital's *generic* voracious appetite for the increase in the rate and mass of surplus value through SE, into a *specific* 'structural' trait of peripheral countries.[4]

Unequal exchange as the essential ground of Latin America's dependency in Dussel's 'Towards an unknown Marx'

Marini's consideration of SE as the *essential determination or ground* of dependency has been called into question by Enrique Dussel, the other author who stands out for his effort at developing dependency theory based on the categorial framework and dialectical method of the Marxian critique of political economy. Without denying the reality of SE as an 'empirically-existing' phenomenon in the periphery of the capitalist world-system, Dussel (2001, 212) points out that Marini 'errs when he confuses a "compensation mechanism" […] with an essential determinant'. By contrast, Dussel argues, 'Marx would have expressed the essential and fundamental simply: Dependency consists of the transfer of surplus value from a less-developed total national capital to a more developed one' (214). In other words, only because of the existence of such international transfer of surplus value, does SE eventually arise as 'a secondary, derivative mechanism' to compensate for the essence of the transfer, which resides in unequal exchange (205).

Now, Dussel is very emphatic that the phenomenon of dependency does not abstractly negate that of competition but, to the contrary, develops it. In this sense, he explicitly postulates that 'dependency is a moment in the competition of capital' (Dussel 2001, 214). Moreover, he adds that competition belongs in the sphere of circulation. For that reason, no surplus value can be generated through competition; the latter can only distribute the value which has been created in production. In effect, through the mediation of competition, the values of commodities take the concrete form of prices of production (which can be higher or lower than the former). In this manner, i.e. through the consequent formation of the general rate of profit, individual capitals with a higher organic composition appropriate part of the surplus value which has been extracted from wage-labourers by capitals from branches of social production with a lower organic composition. But insofar as this process takes place on the world market among 'total national capitals of different levels of development (i.e. of different organic composition and with different average national wages)' (225), it turns out that dependent countries prove to be those in which individual capitals, on average, tend to operate with a lower organic composition, thereby suffering a drain of surplus value into the pockets of 'dominant countries'. On these grounds, Dussel infers that the transfer of surplus value from a less developed to a more advanced total national capital implies that the latter valorises at the expense of the former (217–19). This essentially unequal exchange on the world market constitutes the fundamental basis of dependency.

Nevertheless, Dussel agrees that there are other secondary or derivative modalities of the transfer of surplus value. For instance, this is the case if 'the more developed country, as the only buyer, sets the "international monopoly price" of the product (coffee, for example) at less than the value of the commodity' (Dussel 2001, 228). Also, it could happen that capitals from more developed countries establish a monopoly over the supply of a particular commodity which is not produced in the periphery, which allows them to fix a market price above the respective price of production (as generally happens, according to Dussel, in the case of means of production) (229). Another secondary mechanism for the perpetuation of dependency occurs when individual capitals from more developed countries – i.e. Transnational Corporations (TNCs) – settle in peripheral countries to cater for the domestic market. Insofar as they set into motion a higher productivity of labour than local individual capitals from the periphery, they manage to sell their commodities at lower prices than the corresponding ('national') value or price of production in the respective branch, thereby capturing extraordinary profits that they remit to their central country of origin (230–31). Finally, building on the contributions by Emmanuel and Amin, Dussel mentions a variation of this latter mechanism which takes advantage of national borders through their impact on international differences in wage levels (231). When TNCs produce in the periphery to export their output to central countries, they pocket a surplus profit derived from a lower disbursement of variable capital *vis-à-vis* individual capitals that produce in their respective countries of origin. In a nutshell, through all these arguments, Dussel wants to throw into relief the primordial character of national borders as mediations for the transfer of surplus value. Whether through differences in the average organic composition of capital or wage levels, the demarcation of national spaces of accumulation act as a *fundamental barrier* to the fluidity of the self-movement of capital (224). On these grounds, Dussel concludes, a diversity of *national markets* crystallises which sustains the 'international *social relation* of domination' (224).

Still, Dussel is at pains to avoid lapsing into a 'methodological nationalism' which takes the unity of the world market as the outcome of the external interaction among constitutively autonomous national spheres of accumulation. In this sense, he maintains that from the point of view of the worldwide unity of the process of capital accumulation, the dependency in competition between a peripheral total national capital and a more developed one as part of the world market, is internal or constitutive of each of the asymmetric poles in the relationship (Dussel 2001, 217). Hence, for Dussel there is 'autonomy' of the total national capital within the total *world* capital; however, it is not 'absolute' but 'relative' (218).

On the other hand, Dussel indicates that the relationship of international subordination involved in the concept of dependency does not eliminate the exploitative social nexus between the bourgeoisie and the working class. On the contrary, he stresses that (unequal) international competition is the mediating form which resolves the share of each total national capital in the whole of the surplus value extracted by capitalists from workers across the globe. He thus makes the further point that, unlike the capital-labour relation that produces surplus value, it is not a 'vertical' exploitative relationship between social classes but a 'horizontal' one (Dussel 2001, 221). Yet, he stresses that it is crucial not to lose sight that the relation of dependency remains a social tie of 'international domination', namely: that 'of one capital over another in competition, which produces a transfer of surplus value from the weaker capital toward the stronger' (221). This is the reason why 'competition between total national capitals of different levels of development does not happen naturally with equal willingness on both sides' (221). Rather, the less-developed capital 'is coerced […] to *enter international competition*' (222). Without this moment of coercion, the less-developed total national capital would 'naturally' tend to 'protect itself by refusing competition, fortifying its borders, and establishing a "nationalist" *national monopoly* (within which there may be intra-national competition)' (222).

The weaknesses of Marxist dependency theory

One of the central elements of the ECLAC (Economic Commission for Latin America and the Caribbean) tradition that sedimented as 'received wisdom' of dependency theory was the notion of 'declining terms of trade'. In this sense, in *Dialectics of Dependency* Marini (2022, 125) explicitly maintains that it is a 'well-known fact that the increase in the world supply of food and raw materials has been accompanied by a decline in the prices of these products, relative to the price of manufactured goods'. Additionally, Marini continues, 'it is clear that such a depreciation cannot correspond to the real depreciation of these goods, due to an increased productivity in the non-industrial countries, since it is precisely there that productivity rises most slowly' (125). However, as Iñigo Carrera (2018, 47) perceptively notes, like his ECLAC predecessors Prebisch and Singer, Marini does not offer any shred of statistical evidence on the alleged evolution of the productivity of labour in primary commodities-producing countries *vis-à-vis* so-called industrial ones. Instead, he simply takes it for granted as an indisputable phenomenon, which would only need to be re-signified and explained within the categorial frame of the critique of political economy, in order to incorporate it as a constitutive element of the Marxist version of dependency theory.

But matters are not as straightforward and self-evident as Marini postulates. In fact, in a recent article, Iñigo Carrera presents an empirical estimate of the respective evolution of the productivity of labour in agriculture and manufacturing in the US. It must be borne in mind that this is one of the largest national spaces of accumulation, which does not erect any specific barriers to the increase in the productivity of agricultural labour and which, in addition, is one of the world's greatest exporters of agricultural commodities (Iñigo Carrera 2018, 48–49). In opposition to the 'conventional wisdom' on the 'declining terms of trade' uncritically endorsed by Marini, Iñigo Carrera shows that, although relative prices of agricultural commodities have certainly dropped around 60% *vis-à-vis* those of industrial commodities, 'the productivity of agricultural labour in the US has been continuously growing faster than in manufacturing. Whilst the former multiplied by 35 between 1910–19 and 2000–09, the latter has done so only by 12' (48–49). Hence, when the estimate of the evolution of relative prices between agricultural and manufacturing commodities factors in the movements of the respective productivity of labour, Iñigo Carrera observes that 'net' or 'adjusted' terms of trade turn persistently favourable to agricultural commodities. In effect, after an initial phase of decline between 1910 and 1930, the trend thereafter reverses direction and the 'net terms of trade' of agricultural commodities start to grow. Already in 1970, they had risen above the base year of the historical series, they subsequently peaked during the 1980s and then slightly fell but still remained above the base year ever since (50–51).

Several points crop up in light of these estimates. First, and in opposition to the beliefs of 'dependentistas', the evolution of net terms of trade shows that there has been a continuous *inflow* of extraordinary social wealth into countries which mostly specialise in the export of raw materials and staple foods to the world market. This international flow of value begs the question of why, despite this influx of extraordinary social wealth, those countries tend to lag behind in the capitalistic development of the productive powers of social labour. As we shall see, the answer to this question needs to lay bare the *specific social form* that constitutes this international movement of social wealth, namely: ground-rent. In this respect, it is striking the virtual absence of any significant discussion of the role or ground-rent in the social constitution of the specific modality and potentialities of capital accumulation in Latin America within the 'dependentista' literature, especially considering the importance given by this approach itself to the specialisation in primary production as determinant of the limited potentialities of accumulation in the periphery. And it is even more striking when one bears in mind that the question of ground-rent and its role in Latin America had cropped up in the controversies within dependency theory towards the end of the 1960s.[5]

We shall come back to the role of ground-rent in the determination of the specificity of capitalist development in Latin America in a later section. For the moment, suffice it to say that the mere existence of an inflow of ground-rent in countries specialised in the export of raw materials and staple foods to the world market allows us to call into question another key notion of the dependency tradition, namely: the idea of 'unequal exchange'. In effect, even if we momentarily set aside *differential* ground-rent and only consider *absolute* and *simple monopoly* rents (which are particularly relevant in mining and hydrocarbons production), this suffices to throw into relief aspects of the determination of the international price of primary commodities which, at the very least, should lead us to qualify any possible systematic drain of surplus value through other determinations of international trade that Latin American countries might experience (Iñigo Carrera 2013, 169–70), whether those derived from 'industrial' countries' alleged ability to 'evade the law of value' on a world scale through the establishment of monopoly prices for their products (Marini), or those which stem from the higher average organic composition of the 'more developed total national capitals' (Dussel). Thus, insofar as there is capitalist landed property, the market price of agrarian (and mining) commodities will necessarily tend to stand above the corresponding price of production or even above its value. And this will partially or completely counteract (if not simply reverse) any other possible drain of social wealth that could be mutilating the potentialities of the national processes of capital accumulation in Latin America.

But the existence of ground-rent is not the only peculiarity of social production in the primary sector which calls into question the notion of unequal exchange. First and foremost, with particular relevance for agrarian production, dependency theory's unilateral focus on the effects of the organic composition of capital in the determination of prices of production overlooks the evidently slow capital turnover time in productions which are subject to biological processes currently uncontrollable by human labour. Secondly, even narrowing down the focus to the organic composition of capital, an impressionistic look suffices to cast doubts on the alleged low incidence of constant capital in mining and, even more so, in hydrocarbons production (which are the key export sectors in many Latin American countries like Chile, Bolivia, Perú, Ecuador and Venezuela). And even in the case of agrarian production, although the assumption of a relatively low organic composition might have been sensible in Marx's times, contemporary evidence suggests that such an assumption might be in need of reconsideration. Turning again to the above-cited text by Iñigo Carrera (2018, 66), he observes for the USA that if we take the value of fixed capital disbursed in machinery and buildings and add the amount of circulating capital in inventories, 'the composition of agrarian capital is significantly higher than that of the manufacturing sector from 1925 until 2009, which is the last year of the series under analysis'.

Having raised some initial objections to the two general notions which structure the dependency tradition as a whole, let us now examine more closely the idiosyncrasies of the respective approaches of Marini and Dussel through which they attempt to articulate dependency theory and the Marxian critique of political economy. Marini's fundamental argument about Latin American 'dependent' economies is that their specificity resides in the relative cheapness of labour-power, a phenomenon which he encapsulates in the notion of SE. A first reservation against this view is that had capital found in Latin America a pool of sufficiently cheap and disciplined labour-power, it would have tapped into that reservoir of 'exploitable human material' to undertake world market-oriented manufacturing production. As we shall see in the following section, that is indeed what lay at the basis of the rapid 'late industrialisation' process in East Asia from around the late 1950s or early 1960s onwards. Yet, in Latin American economies, by contrast, world market-oriented production continued (and in South America continues to this day) amply dominated by raw materials and staple foods, whilst the industrialisation process has been (and in South America continues to be) overwhelmingly dominated by an inward-looking orientation to highly protected domestic markets of a specifically restricted size (or, in more recent times, to highly protected regional markets like MERCOSUR).

The other central idea of Marini's does not pertain to the specific 'mode of production' (i.e. SE) but to its corresponding 'mode of circulation', which takes shape in the particular form assumed by the 'cycle of dependent capital'. Analogously to his stance on the 'declining terms of trade', here Marini takes at face value the claims of Latin American development economics (especially the heterodox structuralist views of scholars like Celso Furtado) and simply attempts to incorporate them in the 'categorial frame' of the critique of political economy. The problem is that many of those claims have a questionable empirical basis. As Astarita (2010, 56–57) comments in this regard, 'it is not true that in Latin America consumer durables producing industries were condemned to a limited effective demand comprised of only five or ten percent of the population'. On the contrary, in countries like Argentina, Brazil, Uruguay and Chile a significant part of the working class incorporated those kinds of commodities in their normal conditions of reproduction.

On the other hand, and more importantly, in presenting the expansion of mass consumption as the condition for the realisation of surplus value, that eminently Keynesian train of thought inverts the determination of the value of labour-power and, more generally, the very content of the process of human metabolism subsumed under the capital-form. The alienated finality of capitalist production is not the satisfaction of human needs for use-values, i.e. the reproduction of human life, but the valorisation of capital. The value of labour-power and, therefore, the magnitude and qualitative material composition of the 'consumption basket' of the working class, is thus determined by the mass of commodities which are necessary for the *normal* reproduction of the materiality of all the productive attributes (both technical and 'moral') which must be set into motion to *produce* surplus value for capital.[6] By contrast, in a clearly *underconsumptionist* fashion, Marini's notion that the 'normal' or 'non-deformed' circuit of capital that allegedly obtains in 'industrial countries', requires a sufficiently high wage level to absorb certain commodities (regardless of those which are strictly required to reproduce labour-power in the material conditions demanded by the changing modalities of the real subsumption of labour under capital), presents working-class consumption in an inverted manner, as determined by the necessity to *realise* surplus value in circulation.[7]

Let us now turn to examine Enrique Dussel's approach, which explains the situation of 'dependency' as the outcome of 'transfers of surplus value' that take place through international exchange between total national capitals of different degrees of development, as expressed in the different levels of average organic composition of the individual capitals that operate in each type of national space of accumulation.[8] The first point to make against this view is that the representation of this social process as involving 'unequal exchange', i.e. with what is an eminently *normatively* charged label, involves taking the *necessary form* assumed by the norm which regulates the material unity of the capitalist mode of production, as if it were the abstract 'violation' of what is deemed 'ethically' normal (Iñigo Carrera 2017, 211). Thus, Dussel's 'horror and abomination' in the face of the alleged 'inequality' in the relations established by the individual organs of the global total social capital, implicitly considers that the equivalence which *should immediately govern* the exchange of commodities involves equal *quantities of value* and not of *valorised value*. In other words, the implication of Dussel's approach is that commodities should exchange as simple products of labour and not as products of labour subsumed under capital. As Iñigo Carrera eloquently puts it:

> As simple products of labour, the equivalence in commodity exchange corresponds to their condition as identical materialisations of privately-undertaken socially necessary abstract labour, i.e. to their conditions as values. But commodities […] are the products of capital. As such, their equivalence in exchange does not correspond to their abstract condition as equal values, but to their concrete condition as equally valorised values. From the viewpoint of the organization of social production and consumption in the capitalist mode of production, exchange at prices of production determined as the concrete form of value is the real egalitarian exchange.
>
> (Iñigo Carrera 2017, 211–12)

It follows from this that the fact that a national space of accumulation experiences an outflow of surplus value through international trade by virtue of the average organic composition of capital prevailing within its territory (in turn an expression of the sectoral composition of the productive structure), *does not entail any hindrance to its valorisation capacity*. In effect, the individual capitals that comprise that total national capital yield, on average, the *uniform general rate of profit* as any other capital across the world market. Put differently, the cession in circulation of a portion of the surplus value extracted from the domestic working class, which is directly exploited by a determinate 'collective capitalist' which operates in a certain national sphere, does not mutilate their respective accumulation capacity. Rather, it is the necessary form in which they affirm themselves as solidaristic undifferentiated organs of the *global* total social capital. In this sense, it is quite simply not possible to explain the constitution of national spaces of accumulation with different qualitative modalities and potentialities, based on an attribute which pertains to the simplest determination of the formation of the general rate of profit through the transformation of values into prices of production.

The accumulation of capital on a world scale, the international division of labour and the hierarchical stratification of the interstate system: general foundations of uneven development

Against the backdrop of our critical assessment of the two most sophisticated approaches to the Marxist dependency theory, we can infer a first general conclusion about a shared limitation in their respective accounts of the specifically-limited potentialities and contradictory dynamics of Latin American societies. In a nutshell, these theories fail to elucidate the *immanent* connection between the *essentially global content* of capitalist social relations and the *differentiated national forms* in and through which such social unity is established on a world scale. More concretely, they stop short at the apparent externality in which the inner nexus between global content and national form of the capital accumulation process manifests itself.

In the case of Marini, such externality is expressed in his representation of the specificity of capital accumulation in Latin America as residing in a particular, *nationally-embedded* method of production of surplus value based on the SE of labour, which in turn emerges as an 'adaptation mechanism' through which dependent economies react to the outflows of surplus value that result from the 'unequal exchange' relations that they establish in international circulation with advanced capitalist countries. In other words, for Marini, the production of surplus value is an attribute of each 'national total social capital', with its specificity determined by the *dominant* (i.e. essential but not necessarily exclusive) mechanism of exploitation of the working class. Latin American 'total social capitals' develop their own nationally-based methods of production of surplus value (SE) as a 'functionally-determined' consequence of the methods originally developed in advanced countries (technical progress).

Dussel, for his part, posits the national specificity of 'peripheral societies' as the emergent outcome of the unfolding of a single 'law of value' on a world scale. In turn, the latter is seen as the unitary immanent content which takes concrete form in the sphere of international competition through the unequal exchange between national total social capitals of diverse degrees of development. However, this initially-posited essential global unity is later torn asunder, as he eventually postulates a residual element of 'relative autonomy of the national-form', from which 'dependent countries' are coercively forced out by 'developed countries' in order to compel them to enter into relations of international competition. On this basis, Dussel then ends up representing the action of the state in 'dominated countries' as capable of abstractly negating the 'objective compulsion' of competitive relations on the world market (whether partially and temporarily in the case of 'populist' political regimes, or with full potentiality in the case of revolutionary movements of 'national liberation').

By contrast, we think that a sound comprehension of the patterns of national differentiation that structure the specificity of Latin American societies must part company with the notion of 'autonomy' implicit in both versions of the Marxist dependency theory that we just reviewed. As we shall see below, the key question resides in explaining why and how the immanently global unity of capital accumulation (the content) becomes self-differentiated into national spaces of valorisation of qualitatively varied modalities and potentialities (the form), as it *subsumes* under its movement of formally boundless self-expansion the materially diverse determinations of different territories and human productive forces across the globe, thereby engendering historically-changing constellations of the international division of labour.

As we have seen in the first two chapters, the historical specificity of capitalist production derives from the private and independent form taken by social labour. Social relations thus take the alienated form of powers of the product of labour, and human beings become determined as personifications of those objectified forms of social mediation. This indirect form in which the unity of social labour is established is fully-developed when it becomes capital. In this more concrete form as self-valorising value, the materialised social relation does not simply formally mediate the material life process of human beings, but actually becomes inverted into the very alienated subject of the process of social reproduction and its expansion *in its unity*: the material metabolism of society takes the inverted form of the accumulation of the *total social capital* (Marx 1976, 763).

In the process of renewal of the conditions for its self-valorisation, the total social capital produces and reproduces commodity owners as members of antagonistic social classes (Marx 1976, 723–24; 1992a, 185). In its simplest determination, the class struggle is thus the most general direct social relation between collective personifications of commodities (thereby distinguished as a political form of social relations), which mediates the reproduction of the indirect relations of capitalist production through the generalised commodity-form (hence determined as the economic form of social relations) (Kicillof and Starosta 2007; Starosta 2016a, 216ff.). Although it is a necessary form taken by the reproduction of the total social capital, the antagonistic character of the class relation disrupts the fluidity of the former's valorisation. The establishment of the general unity of social labour must, therefore, take shape through a further objectified form of social mediation, the state, which in bourgeois society confronts commodity owners (the personifications of money-as-capital and of the commodity labour-power), as an apparently external power with the authority and capacity to establish the overall direct regulation of their antagonistic social relations (Iñigo Carrera 2013, 91ff.). The state thus develops as the most concrete political form that embodies the direct organisation of the unity of the conditions of social reproduction in its alienated capital-form. That is, the state is the concrete form of essentially indirect social relations through the valorisation of capital. By virtue of this content, the state becomes the *general political representative of the total social capital*. In brief, capitalist social relations exist as differentiated into economic forms (the autonomised movement of capital commodities on the market) and political forms (class struggle and the state). The latter, far from enjoying 'autonomy' (relative or otherwise), are the necessary mode of realisation of the contradictory content of the economic mode of existence of capitalist social relations. In other words, class struggle and state policies are not to be conceived of as independent, self-subsisting factors that externally modify or influence the workings of the law of value. Instead, they need to be grasped as necessary modes of motion through which the law of value further unfolds beyond the strictly economic forms immediately springing from the indirect nature of the social relations of capitalist production.

Now, as argued in Caligaris (2016), the plan that Marx had outlined for the exposition of the critique of political economy culminated, at least in his most ambitious versions, with a book on the 'World Market' (Marx 1973, 108; 1983, 270; 1987, 261; 1991, 205). Thus, from an early stage, Marx considered capitalism to be a universal mode of production and, consequently, of an *essentially* global character (Marx and Engels 1975, 49; Marx 1992b, 340–41). This immanently global nature of capital does not simply boil down to the immediately observable fact that national markets are connected through foreign trade and investment flows, but means that the *world market* constitutes the 'vital or metabolic environment' for the process of capital accumulation. In other words, the world market is for Marx the only place where the total social capital fully affirms itself as the alienated subject of social production.

Thus, although in its *historical genesis*, the formation of the world market has been the outcome of the confluence of a multiplicity of national processes of capital accumulation (which happened during the phase of the so-called 'primitive accumulation'), once this stage of its becoming achieved completion, the relationship between the global and the national dimensions of capitalist society experienced an inversion: the worldwide unity of the process of accumulation turned into the very general social process whose self-movement is realised through its differentiation into territorially or jurisdictionally demarcated spaces of valorisation in mutual competition (Iñigo Carrera 2013, 57ff.). In other words, the unity of the global total social capital becomes self-differentiated into the circulation processes of distinct national total social capitals. In this way, the competition between individual capitals becomes politically mediated by the direct relations that are established between distinct national states – that is, their 'international relations' (Caligaris 2016, 58). The formation of the uniform world market rate of profit thus takes concrete shape through diverse and historically-changing geopolitical forms. However, this does not change the fact that the immanent content of both international economic relations between individual capitals and international political relations between national states remains the accumulation of the total social capital on a global scale, as the immanent content of the world market (Smith 2006, 193). Geopolitical competition in the 'interstate system' is thus but a further mediated form in which, through their political representation by their respective states, the 'multiplicity' of national total social capitals also asserts their unity as aliquot parts of the global total social capital, i.e. as 'hostile brothers' that partake in the collective exploitation of the international working class. In brief, as an expression of its inherently self-expansive nature, this fetishised social relation is global in *content* and national only in *form* (Clarke 2001).

It follows from this that the *essential determination* of the global dynamics that structure the world market is not one of 'imperialism', understood as a set of asymmetrical or hierarchical *direct political relations* of subordination between 'countries' that structure the interstate system.[9] As perceptively noted by the scholars from the Marxist dependency theory tradition discussed earlier, from the standpoint of the critique of political economy, those asymmetrical international political relations, without being 'empirically or factually' false, actually constitute the *phenomenal forms* of uneven development on a global scale but not its *foundation* (Marini 2022, 125–26). However, and here we part company with those authors, we think that the essential economic content of global uneven development does not reside in the 'unequal exchange' between the respective national total social capitals of centre and periphery (Dussel), or in a process 'led' by the production of relative surplus value in advanced countries to which 'dependent countries' must reactively adapt through particular forms of capitalist development centred on the SE of the working class (Marini).

In our view, the most general economic content which structures the inner global unity of the world market, whose movement takes outward concrete from through the uneven differentiation of national spaces, is the *production of relative surplus value by the global total social capital on a planetary scale*.[10] This eminently unconscious and crisis-ridden social process gives rise to historically-changing constellations of the international division of labour and, as a consequence, to qualitatively differentiated developmental potentialities for each national 'aliquot part' that mediates this social process across the globe. On the other hand, out of this spatial self-specification of the generic potentialities of global surplus value production, varied accumulation capacities do emerge for the diverse concrete modalities it assumes in each national space for the valorisation of capital. More concretely, it limits the specific potentialities of certain national total social capitals to act as immediate active bearers of the development of the productive powers of social labour. In this sense, the respective international geopolitical relations on the world market do not simply take antagonistic forms but become mediated by a stratified interstate system. Nevertheless, however unequal the force carried by each national total social capital in their mutual confrontation in the international arena, the general underlying content of their formally autonomous action when economically and geopolitically competing on the world market, does not revolve around the satisfaction of the interests of 'imperialist powers' or 'core countries' at the expense of 'peripheral or dependent nations'. Rather, it consists of giving course to the production of relative surplus value by the total social capital in its immanent global unity. The latter is, in sum, the essential social determination that is realised in the political form of state policies (domestic and foreign), competitive strategies of individual capitals and class conflict *in all countries*, albeit 'behind the backs' of the antagonistic actions of the personifications involved (that is, social classes and their diverse political organisations, political elites, and/or state managers).

The immanent unity between economic content and political form of the specificity of Latin American societies[11]

Now, as is recognised by virtually all accounts of the history of capitalist development in Latin America, the original subsumption of these territories to the global accumulation of capital was based on the production of agricultural and/or mining commodities for the world market.[12] As Marx remarks in *Capital*, the establishment of this 'classic' modality of the international division of labour (that he labels 'new'), which 'converts one part of the globe into a chiefly agricultural field of production for supplying the other part, which remains a pre-eminently industrial field' (Marx 1976, 580), was determined by the production of relative surplus through the system of machinery of large-scale industry.

In effect, the exceptional natural conditions prevailing in many of these territories allowed for a greater productivity of agricultural or mining labour, thereby resulting in the cheapening of means of subsistence and a lower value of labour-power. However, this form of subsumption of Latin American territories into the global circuits of accumulation was ridden with a contradiction: if, on the one hand, the total social capital enhanced its valorisation by reducing the value of labour-power, on the other this was partly offset by the drain of surplus value, otherwise available for capital's appropriation, flowing into the pockets of domestic landowners in the form of ground-rent. Moreover, to the extent that primary commodities produced in the region have been exported and consumed overseas, ground-rent has constituted a continuous *extraordinary* international *inflow* of social wealth (as opposed to the aforementioned *normal outflows* in the process of *equalisation* of the worldwide rate of profit overly emphasised by 'dependentistas').

Capital was thus driven to overcome this barrier to its accumulation capacity by reshaping those spaces of valorisation in order to recover part of that surplus value, through the establishment of an 'antagonistic association' with local landowners over the appropriation of ground-rent. From being simply a source of cheap raw materials and means of subsistence, those territories became also determined as sources of ground-rent recovery for global industrial capital. The developmental trajectory of these countries has been determined by the historical course of this modality of capital accumulation, not only throughout the so-called agro-export stage but also during the so-called Import Substituting Industrialisation (ISI) phase and, in South America, until contemporary times (Iñigo Carrera 2016, 34–47).

As argued in Caligaris (2016, 66), insofar as 'the political representation of the global total social capital by the state is mediated by the national form taken by the accumulation process' the total social capital's recovery of ground-rent 'must take shape, first of all, in the appropriation of ground-rent by the national total social capital of "resource-rich" countries through its own national state'. This political mediation has been necessary to block the 'spontaneous' course of ground-rent towards landowners through a wide array of state policies that intervene in the circulation of ground-rent-bearing commodities and divert its flow towards industrial capital. Thus, the transfer of ground-rent has been achieved through different policy mechanisms (overvalued exchange rates, export and import taxes, direct state regulation of staple food and raw material prices, etc.), which resulted in the establishment of specific domestic conditions for the circulation of capital within those national territories.[13] Consequently, its appropriation could only be done by industrial capitals operating within those countries and whose circuit realised its final phase (i.e., the sale of commodities) almost exclusively on protected domestic markets of a very limited size *vis-à-vis* world market norms (Grinberg and Starosta 2009, 769). Although this has meant that individual capitals could not reach the scale needed for profitably utilising advanced technologies, they have compensated for the resulting higher production costs by appropriating a portion of ground-rent. In this way, they have valorised at the average rate of profit despite their restricted magnitude and backward technologies. This abundant extraordinary mass of social wealth has systematically complemented the surplus value extracted from the domestic working class to the point of marking the very specificity of the accumulation process in those national spaces.

The modality of the accumulation of capital based on the appropriation of ground-rent in Latin American protected markets has been attractive for domestic capitals that, with the exception of those producing ground-rent-bearing commodities, were not competitive enough to sustain their expanded reproduction by producing for the world market. But additionally, and fundamentally, those markets have proved especially profitable for industrial capitals of foreign origin (i.e., TNCs), which were established there from the mid-to-late-1950s onward. Unlike the internationalisation strategy of TNCs in East Asia (the establishment of 'world market' factories, whether directly or through Original Equipment Manufacturer [OEM] arrangements), foreign capitals in Latin America operated on the smaller scale that those domestic markets required and, given their protected nature, actually made possible. In this way, TNCs in Latin America managed to valorise obsolete fixed capital and accumulate without spending a portion of surplus value in the active development of the productive forces of social labour. However, the other side of this same coin is that the scale of Latin American processes of capital accumulation continued to be structurally dependent on the highly cyclical evolution of the magnitude of ground-rent available for appropriation (hence the widespread 'political and institutional instability' that has historically characterised most Latin American countries, with sharp oscillations between nationalistic populist and/or developmentalist regimes and neo-liberal ones).

This also explains the noticeable lack of dynamism of capital accumulation in the region since the mid- to late 1970s, which was momentarily and only partially reversed during the 'primary commodities boom' of the past decade that came to an end about five years ago (politically expressed in the corresponding shift to the right in, for instance, Argentina, Brazil, and Chile after 2015)[14]: in effect, the mass of ground-rent, especially of agrarian origin, has been, on average, growing at a slower pace than is required by industrial capital in Latin American national spaces of accumulation. As a consequence, the process of capital accumulation in the Latin American countries slowed down or entered into a deep crisis. In this context, and in order to compensate for the slowly growing ground-rent in sustaining industrial capital's profitability, these national processes of capital accumulation have resorted to other sources of extraordinary social wealth, such as the payment of labour-power below its value and the massive inflow of global fictitious capital in the form of mounting foreign debts (the latter made available as a result of the expansion of international liquidity deriving from the long-standing crisis of global overproduction).

Now, since at least the late 1950s, the planetary production of relative surplus value by the total social capital has led to the emergence and gradual development and expansion of a novel configuration of the international division of labour, which has not simply displaced but co-exists alongside the 'classic' modality just sketched out. Premised on the concrete material forms taken by the further automation of the capitalist labour process and advances in means of transport and communication, the so-called New International Division of Labour (NIDL) has revolved around the *international fragmentation of the collective productive subjectivity of the working class* (Fröbel et al. 1980; Iñigo Carrera 2013, 53ff.; Starosta 2016b). Moreover, as a result of its own immanent tendencies, the simplest original form of the NIDL has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class. Each national sphere of accumulation that actively participates in the NIDL, therefore, tends to concentrate on a certain type of labour-power of distinctive 'material and moral' productive attributes of a determinate complexity. Whilst spatially dispersed from each other, they are all collectively exploited by capital as a whole in the least costly possible manner.[15]

Although this more recent global restructuring of the international division of labour had its most emblematic expression in the 'late industrialisation' experience of East Asia since the 1960s (Grinberg 2016), it also had a profound impact in Latin America; paradigmatically in Mexico after the 'debt crisis' of the early 1980s and more recently in Central America and the Caribbean Basin. Thus, despite the similar developmental trajectory of Mexico *vis-à-vis* Argentina and Brazil until the 1980s, in the past three decades, the former country has transformed the specificity of its capital accumulation process. More concretely, it has become a source of relatively cheap and disciplined simple labour-power for industrial capital in general, which exploits it in the material conditions (of scale and technology) needed for competitive world market production (whether directly in Mexico through the *maquilas* regime, or mediately through the international migration of workers into the United States). Hence the contrast with Argentina and Brazil, where capital continued to find it more profitable to valorise on the basis of the appropriation of a portion of ground-rent: this happened either because the specific kind of labour-power it needed was not there or was not cheap enough and/or because the mass of ground-rent was large enough to offset the benefits of a 'structural transformation' in the other direction by providing the source of extraordinary social wealth sustaining those profitable protected domestic markets.

Conclusion

In this chapter, we offered a critical examination of the Marxist dependency theory which centred on two main issues. On the one hand, we called into question the autonomy they more or less explicitly assign to political forms of social relations *vis-à-vis* their immanent economic content (especially in the case of Dussel). On the other, we challenged their inability, despite their best efforts, to transcend all traces of 'methodological nationalism' in their understanding of the global process of uneven development.

To transcend these shortcomings, we offered an alternative approach based on the methodologically-minded reading of the Marxian critique of political economy that we have been unfolding throughout this book. More concretely, we argued that it is necessary to leave behind the aforementioned two-fold notion of autonomy that implicitly or explicitly informs those perspectives. And this means taking the *immanent unity* of the capitalist world market as the starting point of the investigation and, as a consequence, grasping the changing patterns of national or regional differentiation as concrete forms that mediate the unfolding of the contradictory dynamics of the essentially global production of relative surplus value by the total social capital. In turn, the specific political forms prevailing in each country prove to be expressions of the movement of the economic forms taken by global capital accumulation in each national space of valorisation. In our view, these two insights are grounded in one of the most potent scientific discoveries of Marx's critique of political economy, namely, that capital is neither simply a thing (for example, the instruments of production), nor a productive unit or legal entity (such as a firm), nor a social grouping sharing common characteristics and interests (for instance, 'business' or 'the bourgeoisie'). In its general determination as self-valorising value, capital becomes 'the all-dominating economic power of bourgeois society' (Marx 1973, 107), whose 'substratum' is the 'world market […] in which production is posited as a totality together with all of its moments' (227).

Notes

1 This section partly draws on a Spanish version in Starosta and Steimberg (2019).

2 Elsewhere in his work, Marini offers a different formulation of the grounds of SE as the specific form of surplus value extraction in the periphery. See Córdoba and Kozlowski (2017). According to this novel angle on the question, the surge in the demand for food and raw materials up to 1870 propelled an increase in the intensive and extensive productive consumption of labour-power in Latin America to meet that greater demand. As a result, there was a rise in the mass of value produced in the periphery and,

more concretely, an improvement in the terms of trade for Latin America. But these favourable conditions of profitability in dependent countries unleashed an inflow of capital investment, which in turn led to a rising organic composition of capital, a higher productivity of labour, and a fall in the value of domestically produced commodities. Moreover, this process entailed a fall in the rate of profit. It is in this context, according to Marini's new argument, that SE developed as an adaptative response to the fall in profitability in Latin America.

3 Strictly speaking, Marini later qualifies this statement and puts into relief the interweaving of SE and the development of the productivity of labour. In other words, as Marini (2022, 164) himself clarifies in the *Postscript* to the *Dialectics of Dependency*, it is not a matter of two mutually exclusive forms of exploitation but of the 'greater or lesser occurrence of the forms of exploitation and their specific configuration they assume'. The characteristic feature of the periphery is therefore not the complete or absolute prevalence of SE but its relative dominance, which nonetheless reaches the point of marking the qualitative specificity of capital accumulation in the region.

4 Osorio, who probably is one of the leading contemporary scholars within the Marxist tradition of dependency theory inaugurated by Marini, adds that the resulting lower wages act as a barrier for the introduction of scientific and technical innovations. The reason for this is that the potential savings in paid living labour do not make up for the increase in constant capital entailed by such displacement of living labour. See Osorio (2017, 49). In this way, capital in the periphery does not immediately face the need to substitute dead for living labour.

5 See Chapter 9 of this book. As recognised by contemporary scholars, who are otherwise broadly sympathetic to dependency theory (Katz 2019), Marini in particular completely overlooks the role that ground-rent might play in the determination of the specificity of capital accumulation in Latin America. More recently, some of his disciples have attempted to consider this role (Osorio 2017). However, as Iñigo Carrera (2019) notes, Osorio's arguments rest on weak foundations in his understanding of the general determinations of ground-rent as a capitalist social form.

6 See Chapter 5 of this book for a fuller discussion of this.

7 In addition, note that this presupposes the absurd idea that the condition for capital to produce surplus value would be that it *relinquished* part of that mass of objectified unpaid labour-time that it extracts from the working class through their exploitation. But this could only occur under the extremely specific circumstances that the resulting multiplication of the scale of production led to such a fall in the value of 'wage-goods', that it redounded in an increment of surplus value. It goes without saying that it is highly unlikely that a process like this systematically took place in the concrete history of capital accumulation in 'central countries'.

8 Strictly speaking, we have seen that Dussel also mentions those transfers of surplus value derived from national differences in wages. However, in a similar vein to SE more generally, he considers that those other transfers are somehow secondary or derivative *vis-à-vis* the fundamental one based on differences in the organic composition of capital. Be that as it may, for a critique of explanations of unequal exchange based on the relative cheapness of labour-power in certain national spheres of valorisation, see Iñigo Carrera (2013, 171; 2017, 217–23).

9 For a contemporary contrasting view, which attempts to reassert the essentiality of the notion of imperialism, see Milios and Sotiropoulos (2009).

10 For a similar argument from a different perspective, see Burnham (1994) and Howe (1981).

11 This section draws on Starosta (2019).

12 Notably in the original colonial forms of subsumption, the production of the money-commodity would be a key determining element in the specificity of the valorisation of capital in the region.

13 See Iñigo Carrera (2007) and Caligaris (2016) for a detailed account of those policies and their role in transferring ground-rent to industrial capital (and the former bibliographical source, in particular, for statistical evidence supporting this argument for the case of Argentina).

14 For the so-called Pink Tide in South America, see Grinberg and Starosta (2014) for Argentina and Brazil, and Purcell (2016) and Dachevsky and Kornblihtt (2016) for Ecuador and Venezuela.

15 Note, additionally, that this point applies to intellectual labour as well (Huws 2014).

International Political Economy Series

The New International Division of Labour

Global Transformation and Uneven Development

Edited by Greig Charnock and Guido Starosta

International Political Economy Series

Series Editor

Timothy M. Shaw
Visiting Professor at the
University of Massachusetts Boston, USA, and
Emeritus Professor at the
University of London, UK

The global political economy is in flux as a series of cumulative crises impacts its organization and governance. The IPE series has tracked its development in both analysis and structure over the last three decades. It has always had a concentration on the global South. Now the South increasingly challenges the North as the centre of development, also reflected in a growing number of submissions and publications on indebted Eurozone economies in Southern Europe. An indispensable resource for scholars and researchers, the series examines a variety of capitalisms and connections by focusing on emerging economies, companies and sectors, debates and policies. It informs diverse policy communities as the established trans-Atlantic North declines and 'the rest', especially the BRICS, rise.

ACKNOWLEDGEMENT

Chapter 2 is a translation of the following, adapted and produced by the editors with the permission of the copyright holder:

Iñigo Carrera, J. (2013) ‘Capítulo 5: La tasa general de ganancia y su realización en la diferenciación de los capitales industriales’, in *El capital: razón histórica, sujecto revolucionario y conciencia*, second edition (Buenos Aires: Imago Mundi).

CONTENTS

1 Introduction: The New International Division of Labour and the Critique of Political Economy Today 1

Part I Capital and the International Division of Labour 23

2 The General Rate of Profit and Its Realisation in the Differentiation of Industrial Capitals 25

3 The Global Accumulation of Capital and Ground-Rent in 'Resource Rich' Countries 55

4 Revisiting the New International Division of Labour Thesis 79

Part II Country Case Studies 105

5 'Post-neoliberalism' in the International Division of Labour: The Divergent Cases of Ecuador and Venezuela 107

6 The New International Division of Labour in 'High-Tech Production': The Genesis of Ireland's Boom in the 1990s 127

7 New International Division of Labour and Differentiated Integration in Europe: The Case of Spain 157

Part III Sectoral Case Studies 181

8 Transnational Corporations and the 'Restructuring' of the Argentine Automotive Industry: Change or Continuity? 183

9 Patterns of 'State-Led Development' in Brazil and South Korea: The Steel Manufacturing Industries 215

Index 245

NOTES ON THE CONTRIBUTORS

Gastón Caligaris gained his PhD in Social Sciences from the University of Buenos Aires. He currently holds a postdoctoral research scholarship from the National Council of Scientific and Technical Research (CONICET), Argentina, and is based at the National University of Quilmes. He also teaches in the Social Science and Philosophy and Letters Faculties of the University of Buenos Aires. He is co-editor of *Economic and Political Relations: Contributions for the Study of their Unity based on the Work of Karl Marx* (2012, in Spanish), and has published various articles and book chapters in national and international academic presses.

Greig Charnock is Senior Lecturer in International Politics at The University of Manchester, where he teaches international political economy, the politics of globalisation, and Marxist critical theory. His most recent research has engaged the 'open Marxism' approach with critical theories of the production of space, and in analyses of crisis formation and management in Spain. He is co-author of *The Limits to Capital in Spain* (2014), and has published articles in such journals as *Antipode*, *Society and Space*, the *International Journal of Urban and Regional Research*, *Historical Materialism, New Political Economy*, and *South Atlantic Quarterly*. He is a member of the editorial board of the journal of the Conference of Socialist Economists, *Capital and Class.*

Alejandro Fitzsimons teaches Economic Sociology at the University of Buenos Aires. He is currently a post-doctoral scholar at the National University of Quilmes, with a research project on the evolution of the automotive and oil industries in Argentina between 1960 and 1990. His doctoral research studied the forms of valorisation of foreign capital in Argentina in the late 1950s and early 1960s. Other research interests include the dynamics of capital accumulation in Argentina after the crisis of 2001, and general topics of value theory. He is co-editor of

Economic and Political Relations: Contributions for the Study of their Unity based on the Work of Karl Marx (2012, in Spanish).

Tomás Friedenthal holds a PhD in Economics from the University of Buenos Aires, where he currently teaches Industrial Organisation in the Faculty of Economic Sciences. His research interests are in the fields of the political economy of development, monetary theory and method.

Nicolas Grinberg is a Research Fellow for Argentina's National Scientific and Technical Research Council (CONICET). He is based at the Institute for Advanced Social Studies of the National University of San Martín where he also teaches Development Economics. He holds a PhD in Economic History from the London School of Economics and Political Science. His research interests are in the political economy of development (with a regional focus in Latin America and East Asia). He has published his work in the *International Review of Applied Economics*, the *Journal of Contemporary Asia*, *New Political Economy*, and *Third World Quarterly*, amongst other outlets.

Sebastián Guevara is Professor in the Faculty of Social Sciences at the University of Buenos Aires, and a researcher for the National Council of Scientific and Technical Research (CONICET), Argentina. His research examines trade unions actions as a concrete expression of the accumulation of capital, in Argentina and the rest of Latin America. At the same time, he studies the automotive industry in Argentina and Brazil as particular expressions of the form in which capital accumulation has developed in the region. His principal publications to date are in the journals *Razón y Revolución*, *Revista E-L@tina*, *Studia Politicae*, and *Revista Política Hoje*.

Juan Iñigo Carrera is an independent researcher and director of the Centre for Science as Practical Criticism in Buenos Aires, Argentina, where he leads workshops on Marx's *Capital*. He also leads courses and research seminars on the critique of political economy, capital accumulation and its political forms in Argentina, and dialectical method at the University of Buenos Aires and the General Sarmiento National University. He is author of the books *Capital: Historical Reason, Revolutionary Subjectivity and Consciousness* (2013), *Child Labour and Capital* (2008), *Knowing Capital Today: Using 'Capital' Critically, Vol. I* (2007), *The Economic Formation of Argentine Society: 1882–2004* (2007), and *Dialectical Knowledge* (1992) (all in Spanish), and has published numerous articles and chapters in national and international books and journals.

Thomas F. Purcell is Senior Lecturer in Politics and International Relations at Leeds Beckett University, where he teaches courses in the area of Politics and Applied Global Ethics. Until recently, he was Sub-Director of the National Centre for Strategies for the Right to Territory (CENEDET) based at the Instituto de Altos Estudios Nacionales, Quito, Ecuador. Prior to this, he held research positions at the Universitat Oberta de Catalunya, and at the Universities of Manchester and Nottingham. His research to date has examined the specificities of capitalist development in Ecuador and Venezuela, and also the political economy of Spain and the Eurozone crisis. He is co-author of *The Limits to Capital in Spain* (2014), and has published several book chapters and articles in journals such as *Geoforum*, *Historical Materialism*, the *International Journal of Urban and Regional Research*, *Latin American Perspectives*, and *Science and Society*.

Ramon Ribera-Fumaz is Senior Lecturer in the Department of Economics and Business and Director of the Urban Transformation Research Group at the Internet Interdisciplinary Institute, both at the Universitat Oberta de Catalunya. He has authored and co-authored numerous publications on the geographies of capitalism, urban transformation, technology, the knowledge economy, and culture; and in such journals as *Society and Space*, the *European Journal of Urban and Regional Studies*, the *International Journal of Urban and Regional Research*, and *Progress in Human Geography*. He is co-author of *The Limits to Capital in Spain* (2014).

Guido Starosta is Professor in the History of Economic Thought at the National University of Quilmes and member of the National Council of Scientific and Technical Research (CONICET), Argentina. He has previously held teaching and research positions at the Universities of Manchester and Warwick. His research interests are in the political economy of development (with a regional focus on Latin America), and his work has appeared in *Antipode, New Political Economy*, and *Third World Quarterly*. He is currently investigating economic and political forms of the accumulation of capital in Argentina under 'Kirchnerism'. He also works on issues of method and subjectivity in the Marxian critique of political economy. He is author of *Marx's* Capital, *Method and Revolutionary Subjectivity* (2016) and co-editor of *In Marx's Laboratory* (2013). Other publications from this strand of research have appeared in *Capital and Class*, *Historical Materialism,* and *Science and Society*.

CHAPTER 1

Introduction: The New International Division of Labour and the Critique of Political Economy Today

Greig Charnock and Guido Starosta

> Thus, from the bare enumeration of some of the more glaringly obvious features of the present-day world economy, it can be seen that the old or 'classical' international division of labour, by which the underdeveloped countries were on the whole incorporated into the capitalist world economy as mere raw materials suppliers, no longer exists. The underdeveloped countries are increasingly chosen as sites for manufacturing industries producing goods that are competitive in the world market.
>
> … This tendency will be designated the '*new international division of labor*' (to be considered as an on-going, not a completed, process) (Fröbel et al. 1978: 845, 849).

In a recent anthology of his essays on *Global Capitalism* (2015) Hugo Radice recounts how in the 1960s and early 1970s progressive, broadly Marxist, scholarship fell short of providing a satisfactory means of understanding what was by then a rapidly changing world. The debates

back then, he summarises, ‘had little to say directly about the transformations of production and work within firms, or about the political relations between organised economic interests and the state, while international economic relations between states were understood firmly in nineteenth century terms of autonomous and mutually antagonistic powers, great or small’ (Radice 2015: 9). Yet profound and lightning-paced transformations in worldwide production and trade were indeed palpable to any observer back then, and by the mid-1970s Marxist scholars in the UK and beyond were beginning to engage in highly productive—and still influential—debates on the labour process, state theory, and alternative political strategies in the context of deep world recession and heightened social and political tensions across much of the West. Radice recalls, in particular, his participation in a 1974 workshop in Starnberg, Germany, ‘at which Otto Kreye and his colleagues presented the first results of their project on the new international division of labour’. This work, he confirms, was to become ‘very influential for progressive scholarship on global capitalism’ (Radice 2015: 9).

The new international division of labour (NIDL) thesis developed by Folker Fröbel, Jurgen Heinrichs, and Otto Kreye very much stands out as one of the most influential and widely debated contributions at the forefront of discussions on late-industrialisation and global production long into the 1980s and 1990s. Based on their empirical studies in the 1970s, Fröbel, Heinrichs, and Kreye’s work seemed to capture extremely well the transformations in the world market taking place by the beginning of that decade, and very rapidly caught the attention of most analysts of international political economy (IPE) and the changing geographies of global capitalism. Although the argument in their book *The New International Division of Labour* (published in English in 1980) rested on very distinctive theoretical foundations and arguments, reviewed below, the expression ‘new international division of labour’ was to somehow acquire a life of its own and soon became very much a part of the working vocabulary of most scholars empirically concerned with global processes of industrial restructuring—a kind of conceptual shorthand to encapsulate what were regarded as the main developments in the world economy at that time. The ‘NIDL’ thus became a catchphrase, widely accepted and loosely used (sometimes by default) to *describe* the novel configuration of the capitalist world market, but without always making a self-conscious effort to acknowledge or flesh out the particular conceptual approach being deployed to *explain* this empirical phenomenon and its subsequent developments.

In a nutshell, the popularised version of the NIDL thesis consisted of the following stylised account of the process of global restructuring. Faced with declining profitability in advanced capitalist countries (mainly due to rising wages), transnational corporations (TNCs) started to relocate labour-intensive manufacturing to the then, so-called, Third World, thus acting as a major factor in the industrial decline that seemed to prevail in the former countries in the late 1970s and early 1980s. 'Third World' countries, for their part, provided TNCs with a huge potential reserve of low-paid and disciplined workers. Combined with technological advances in the means of communication and transport, the increasing fragmentation of production processes and the consequent simplification of semi-skilled and unskilled tasks created a tendency for the establishment of export-oriented 'world market factories' in the 'Third World'. Accordingly, the story went on, the classical international division of labour (CIDL)—revolving around the polarisation of the world economy into an industrialised 'core' and a dependent 'periphery' confined to the role of supplier of raw materials and staple foods—had been superseded by the NIDL, with an industrialised but still dependent Third World, and a 'First World' oriented to a service-based economy, which could not absorb the resulting unemployed population.

The NIDL thesis remained highly influential into the 1990s but—if the scant number of studies published in the last decade dealing directly with the NIDL is any indication—the thesis has since become passé. Undoubtedly, this can be explained in part by changing fads and the development of new lines of inquiry and debate among academics. Yet it is also the case that some scholars had started to put forward strong reservations against the NIDL approach by the 1990s—prompted principally by some empirical developments which seemed to contradict the major claims of the NIDL thesis. The 'impressive' developmental record of the first generation of Asian Tigers (especially South Korea), in particular, seemed to undermine a theory that put export-oriented industrialisation based on extremely low wages in labour-intensive industries at the heart of its argument. More broadly, as many critics have rightly highlighted, the initial formulations of the NIDL thesis contained untenable sweeping generalisations, which could not account for national differences in the developmental path of many countries. The industrial upgrading of the first generation of Asian Tigers, for example, would eventually include relatively complex, capital-intensive sectors rather than simply unskilled-labour-intensive ones, as the stylised version of the NIDL that became common currency appeared to suggest.

While accepting the veracity of some of the criticisms levelled at the original NIDL thesis and the version of it that became common currency by the 1990s, we believe that it now deserves to be revisited. We propose that a *properly reconsidered and revised* NIDL thesis can still shed light on the specificities of capitalist development in various parts of the world today, as well as the nature of uneven development across the capitalist world market. Taken together, the contributions to this book represent the basis for such a reconsideration of the NIDL thesis which rests upon the Marxian distinction between the global economic *content* that *determines* the constitution and dynamics of the international division of labour, and the evolving national political *forms* that *mediate* its development. More specifically, the book argues that national developmental processes across the world have been but *an expression of the underlying essential unity of the production of relative surplus-value on a world scale.* The fact that the approach taken in this book is rooted in the critique of political economy originally developed by Karl Marx over 150 years ago does not detract from its contemporary significance. Moreover, a revised NIDL thesis as put forward in this volume represents an original contribution to key debates in international and critical political economy, insofar as, firstly, its theoretical foundations lie in research that moves to some extent beyond Marx; and, secondly, it departs in significant ways from not only Fröbel and his colleagues, but also a variety of contemporary approaches that seek to understand the nature of—and the relation between—global transformation and uneven development.

From the Critique of Political Economy to a *New* New International Division of Labour Thesis

The book draws its inspiration from innovative theoretical scholarship that has emerged under the auspices of the Centre for Research as Practical Criticism (CICP), based in Buenos Aires, Argentina, and especially the work of the independent scholar Juan Iñigo Carrera. This work, which is only just recently beginning to appear in Anglophone literature—in part, because it has been developed outside of formal academic structures and networks[1]—represents a thorough re-examination of Marx's critique of political economy and its dialectical-methodical foundations. While drawing upon Marx's fundamental insight into the determination of capital as the immediate subject of the organisation of the process of social life, it also moves some way beyond it so as to cast fresh light on global transformation and uneven development in recent decades, as well as to offer ground-breaking research on the emancipatory subjectivity of the working class (a theme we do not broach directly in this book but see, for example, Starosta 2016). The following section outlines the basic contours of the approach pioneered by Iñigo Carrera.

Capital, the System of Machinery and the International Fragmentation of the Productive Subjectivity of the Global Working Class

As Starosta explains in Chap. 4, one of the most potent scientific discoveries of Marx's critique of political economy was that capital is neither simply a thing (for example, the instruments of production), nor a productive unit or legal entity (such as a firm), nor a social grouping sharing common characteristics and interests (for instance, business or the bourgeoisie). In its general determination as self-valorising value, capital is actually a materialised social relation between commodity owners differentiated into social classes, which, in its fully developed form as the total social capital, becomes inverted into the (alienated) subject of the unity of the process of social reproduction and its expansion (Marx 1976: 763). Thus, *capital* is essentially the movement of the self-expansion of the objectified general social relation between private and independent human beings which, in its own process, produces and reproduces the latter as members of antagonistic social classes (Marx 1976: 723–4; Marx 1992: 185). All moments of the human life-process thus become inverted into material bearers of the life-cycle of capital, or they become forms assumed by the flow of value in its circulatory process. Subsumed under the capital-form, the alienated content of social life becomes the production of surplus-value or the formally boundless quantitative progression of the general reified form of social mediation (Marx 1976: 251–7).

Although this content governs the movement of capital as a whole or as an alienated collective power, the *total (global) social capital* is nonetheless the product of the private and independent form taken by social labour. The general unity of the movement of the total social capital cannot be established immediately. It is thereby indirectly established through the exchange of commodities resulting from the apparently autonomous actions of individual capitals in competition with each other, as each of them pursues the maximisation of its profitability through the expanded reproduction of their formally independent cycles of valorisation. In their simplest form, those cycles can be represented through the well-known general formula of capital:

$$M - C \begin{matrix} \text{LP} \\ \\ \text{MP} \end{matrix} \ldots\ldots P \ldots\ldots\ldots C - M + \Delta M$$

Where M = money capital, C = commodity capital, P = productive capital, LP = labour power, MP = means of production. More specifically, the concrete form in which individual capitals assert their class unity as 'aliquot parts' of the total social capital is the process of formation of the general rate of profit (Marx 1981: 298–300, 312). This is the inner or essential determination of the general social relation between capitalist firms (or individual capitals).

The territorial or spatial dimension of the accumulation process—and the changing forms of the worldwide division of labour—therefore cannot be seen as being *determined* by the conscious locational 'strategies' of TNCs faced with given qualitative national and regional differences, in turn seen as established by allegedly autonomous state policies. Instead, it needs to be grasped as an expression of the underlying formal and material unity of the essentially global contradictory dynamics of the accumulation of the total social capital through the production of relative surplus-value, which are *economically mediated* by relations of competition among individual capitals like TNCs (again, as opposed to *determined*), on the one hand, and *politically mediated* by the policies of the nation state on the other. These contradictory and crisis-ridden dynamics, which, in their most developed form as large-scale industry, fundamentally *entail the permanent revolution in the modes of exertion of the labour power of individual workers and of their articulation as a directly collective productive body or organism* (Marx 1976: 617), lie at the heart of the changing historical forms of the international division of labour.

The production of relative surplus-value in the form of large-scale industry entails four divergent tendencies in the development of the productive attributes of the global working class (Iñigo Carrera 2013: Chap. 2). First, it expands the productive subjectivity of the part of the collective labourer responsible for the advance in the conscious control of the movement of natural forces (that is, science) and its technological applications in the directly social organisation of the immediate production process.[2] Although not explicitly addressed by Marx in *Capital*, the benefit of historical hindsight makes it very easy for us to recognise how the total social capital deals with its constant need for the development of the productive powers of science and for the conscious organisation of the increasingly social labour process, namely, by engendering a special partial organ of the collective labourer (see Starosta 2016: Chap. 8). Capital requires from these workers ever more *complex* forms of labour. As much as those discussed in *Capital*, these are also 'immediate effects of machine production on the worker' (Marx 1976: 517). Needless to say, inasmuch as this expanded productive subjectivity is nothing more than a concrete form of the production of relative surplus-value, the exercise of newly developed intellectual productive powers is also inverted into a mode of existence of capital in its movement of self-valorisation. Moreover, sooner or later many of these intellectual dimensions of living labour will also experience automation (or knowledge codification) and therefore become relatively simplified. As we shall see later in this book, this latter aspect has been central to the more recent phases in the evolution of the NIDL (as shown in Chap. 6 through a discussion of the Irish software industry).

Second, it tends to degrade the subjectivity of those workers that acquire and exercise their increasingly simpler manual or experienced-based productive attributes in the direct process of production. Indeed, large-scale industry is based on the objectification of *tacit* knowledge, previously embodied in the manual industrial worker and largely acquired through lengthy on-the-job, learning-by-doing processes, as an attribute of the system of machinery (Huws 2006). In this sense, the impact of capitalist automation certainly tends to be one of 'deskilling' or degradation of direct production work through the objectification of formerly manual tasks as functions of machines. Yet the effect of increasing automation has not just been one of deskilling. It has been mixed, also entailing a certain creation of new skills required by capital even from direct production workers. The key point, however, is that these newer skills have been of a different *kind* from those that have been eroded. While the older skills tended to be based on the *particularistic* development of the productive subjectivity of wage-workers (both manual and intellectual) as a result of the practical experience of machining in the direct process of production, the newly created skills tend to revolve around the *universalistic* dimension of the productive quality of labour-power, whose development is achieved in the general process of education and socialisation that precedes its actual application in the production process. For instance, and crucially for the general argument developed in the book, the ‘microelectronic revolution’ that is at the basis of the NIDL has entailed not only the degradation of the particularistic dimension of direct production work but also the emergence and generalisation of, so-called, soft or generic skills (see Ramioul 2006), such as familiarity with computers and flexibility or individual initiative in problem-solving or decision-making (Balconi 2002).

In the third place, while the new technologies have not resulted in the total elimination of manual labour from automated processes of production (Alcorta 1999: 164), they have recreated the conditions for the extended reproduction of what Marx called the ‘modern manufacturing division of labour’, that is those non-mechanised tasks and labour processes acting as an ‘external department’ of large-scale industry proper as the dominant form (Marx 1976: 588ff). This tendency has been fundamental for initial stages of the NIDL, which are the ones that Fröbel and his colleagues accurately but one-sidedly captured in the 1970s.

Fourth and last, the production of relative surplus-value through the system of machinery leads to the multiplication of the surplus population relative to the needs of the accumulation process, which also constitutes a transformation of productive subjectivity produced by the automation of large-scale industry (see Marx 1976: 553–75). More specifically, this tendency represents the most extreme case of material mutilation of the productive attributes of the working class resulting from capital accumulation, that is, not simply their degradation but their outright non-reproduction. Yet, it is from this tendency that the global pool of cheap but disciplined labour power, which has been central for the original constitution and evolution of the NIDL, has eventually derived.

What all the contributions to this book share is a conviction that the foundation of the uneven spatial differentiation of global capitalism must be searched for in these changing forms of the exploitation of the global working class by the total social capital, through the transformation of the material forms of the capitalist production process. The latter is, in our view, the *general content* that is realised in the political form of state policies (domestic and foreign) and class conflict, albeit behind the backs of the antagonistic actions of the personifications involved (social classes and their diverse political organisations, capitalist firms, ‘political elites’ and/or ‘state managers’). Taking their cue from Iñigo Carrera’s original approach, all the authors in this book see the transformations associated with NIDL as being products of the total social capital's drive to enhance the production of relative surplus-value on a world scale through the development of labour productivity, which finds its most advanced expression in the mechanisation of large-scale industry. Succinctly put, Iñigo Carrera's fundamental argument is that the 'essential' general content that defines the NIDL, and which has been reproduced under its evolving historical configurations since the 1950s until the present time, consists in the *international fragmentation of the productive subjectivity of the working class* (Iñigo Carrera 2013). Thus, as a result of its own immanent tendencies, the simplest original form of the NIDL—which we think Fröbel and his colleagues were right to identify as signifying an on-going process—has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class (through their impact upon their general conditions of reproduction and condensed in the so-called 'historical component' of the value of labour-power). Each country therefore *tends* to concentrate a certain type of labour-power of distinctive 'material and moral' productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital as a whole in the least costly possible manner (Grinberg 2011: 35–6). Production in specific industrial sectors has thereby expanded in some countries while contracting in others where new and more advanced sectors have developed, following a rhythm determined by the evolution of two main factors, that is, technological change and relative cost and productive attributes of national labour forces.

This different constellation *does not* involve the transcendence of the NIDL, as many of the critics of the original thesis have suggested (see Chap. 4), but instead represents a more complex form assumed by the same general content. This was the content that the original formulation of the NIDL thesis by Fröbel, Heinrichs, and Kreye failed to uncover, influenced as those authors were by dependency and world-systems theories, and the view that different countries and regions of the world achieve different levels of development on the structural basis of 'unequal exchange'. And it is this content that has generally eluded alternative international and critical political economy approaches that seek in their own way to explain the specificity of national development and the relations between distinct national 'capitalisms' under conditions of 'globalisation' or of 'combined and uneven development'.

The Significance of This Approach for a Distinctive Understanding of Global Transformation and Uneven Development

We think that, whatever its shortcomings, the early debate over the NIDL in the 1980s (in particular, the contribution by Fröbel, Heinrichs, and Kreye) was indeed on the right track as regards grasping the specific nature of the recent transformations of the process of capital accumulation on a world scale. Thus, it actually provides richer material and a more fruitful starting point for a critical investigation of the determinations underlying the, so-called, globalisation process than many other contemporary international and critical political economy analyses. In this sense, we feel that the question of the NIDL should be put back on the agenda for a robust theorisation of global transformation and uneven development. There is no doubt, as conceded above, that the original debates around the NIDL left many theoretical and empirical questions unresolved. In particular, no contribution managed properly to account for the process of national differentiation as an expression of the underlying essential unity of the accumulation of capital on a world scale. The debate, in short, never resolved the tension between national and global dimensions in the articulation of the international division of labour. The significance of this book, then, is that taken together the contributing authors provide a basis for an alternative critique and reformulation of the NIDL thesis that, first, recovers what constituted its main achievement and which has been forgotten by contemporary theorising; namely, the understanding of national differentiation as an expression of the essential unity of the capitalist world system. Second, and by drawing on a particular reading of the Marxian critique of political economy grounded in the work of Iñigo Carrera, we believe the book provides a more distinctive foundation for the conceptualisation of that unity than can be found in Fröbel et al.'s *marxisant* world-systems theory. Let us elaborate.

Drawing directly upon the work of 'monopoly capital', 'world-systems' and 'dependency' theorists, Fröbel and his colleagues conceptualised the 'unequal development' they believed to be central to world capitalism in descriptive terms of: 'The splitting up of the capitalist social formation into "centre" and "periphery", and also possibly "semi-periphery", both intra- and inter-nationally, that is, the development of an international division of labour with different forms of control over labour for different types of production in different regions of the capitalist world economy'

(Fröbel et al. 1980: 32). In our view, attempts by world-system theorists to explain unequal development proceeded from a problematic theoretical-conceptual distinction between core and periphery. They sought to derive underlying, structural relations between different countries and regions on the basis of empirical evidence which suggested that capital-intensive production was concentrated in the core, that labour-intensive production was concentrated in the periphery, and that the international exchange relations between the core and periphery ensure the continuous development of the former at the expense of the latter.[3] Alongside, or overlaying, these international economic relations, they posited unequal political relations between countries engaged in competitive measures to promote or protect their own industries to the detriment of other countries' industries. At the root of this dualistic conceptualisation of unequal economic and political international relations is an analytical distinction between economics and politics that Radice (2009: 36) rightly, in our view, problematises for its confinement of 'class struggle to the realm of "politics", not realising that the existence of a separate realm of politics is in itself a condition of existence of capitalism'. Furthermore, this conceptualisation assumes that the 'central structural feature of "the economy" is the division of labour *in society*'—whether in national or international form—'rather than in manufacture, to use Marx's careful distinction' (Radice 2009: 34). In other words, it is *capital*—understood as an essentially global process—and not the external and contingent political and exchange relations established between a multiplicity of national states themselves, that *determines* their development. And it is capital's thirst to enhance the production of relative surplus-value, on the basis of the development of large-scale manufacturing and the fragmentation of the international working class, which is at stake in the historical development of the international division of labour, not the reproduction of relations of unequal exchange between domestic and international classes that are somehow socially and politically constituted outside of the global process of accumulation (see Chap. 2).

In any case, the fate of the NIDL thesis was not decided by critical theoretical engagement over the dubious assumptions of world-systems and dependency theories. Indeed, the demise of the NIDL thesis during the 1990s went hand-in-hand with a discernible move away from the consideration of *any* question of the structural unity of the global accumulation of capital by IPE and cognate literatures, and instead turned towards a widespread focus on national state institutions as autonomous drivers of economic development. Not least under the influence of neo-classical economists (such as Krueger 1990; Ranis 1989; Stiglitz 1996; World Bank 1993) and statist international political economists (notably, Amsden 1989; Evans 1995; Rodrik 1994; Wade 1990; Weiss 1998) who dominated debates on the efficacy and resilience of market-led co-ordination versus *dirigiste*, or state-led, development in the context of 'economic globalisation' (see Grinberg 2013: 173–8). As this debate ran out of steam in the late 1990s, scholars working in development studies and economic geography then embarked upon richly detailed research into global commodity chains, as a means of examining the impact of globalisation upon industrialisation in the developing world. While the foundational texts in this new paradigm were actually intellectually rooted in the lineage of monopoly capital and world-systems theory, the bulk of the emergent literature then arguably became highly descriptive and/or tended to focus on conceptualising industrial or business organisation on a 'network' basis (that is, based on the pure contingency of immediate direct social relations) and to the complete eschewal of the question of the constitution of 'commodity chains' and, later, 'value chains' and the dynamics of the global system as a whole (Starosta 2010). Meanwhile, in the IPE literature of the 1990s the question of explaining capitalist diversity became dominated by 'new institutionalist' approaches—not least the 'varieties of capitalism' approach pioneered by Hall and Soskice (2001)—which further compounded the tendency to focus upon the apparently autonomous constitution of individual capitalist states' institutional forms, at the expense of the consideration of what makes them 'capitalist' in the first place and the 'constitutive elements they hold in common' (Coates 2014: 21).

To be fair, a new generation of critical IPE and international relations scholars in recent years has at least sought to rectify the lack of a substantive theorisation of global transformation and uneven development in dominant debates, couched in questions of 'capitalist diversity' (Bruff and Ebenau 2014) or of 'uneven and combined development' (see Allinson and Anievas 2009). For us, however, these contributions have yet to offer a convincing, substantive basis for a 'unified field theory' of uneven development and the ever-changing geographies of capitalism—a necessity famously identified by David Harvey (2005: 58–9; see also Rioux 2015: 508; Smith 1989). Insofar as they do represent a welcome return to older, sidelined debates and canonical Marxist and *marxisant* literature, and an even more welcome exposé of the ideological nature of mainstream approaches, these new contributions ultimately run the risk of reproducing in new guises the problems we argue were already inherent in the classic literature: principally, in terms of explaining the concrete forms of 'variegated national capitalisms' and uneven development through the strategic and conscious action of key agents and 'social forces' that are somehow constituted outside of the process of capital accumulation; or in terms of resorting to the theory of 'unequal exchange' to explain 'underdevelopment'; or in terms of failing to *explain* the social determination of 'uneven and combined development', other than by means of a prior reliance upon the primacy of this under-theorised, abstract and trans-historical category.[4]

We suggest that the approach taken in this book can indeed provide such a unified field theory. By deciphering the national forms taken by the general content of an historically specific mode of the reproduction of total (worldwide) society, on the basis of the fragmentation of the productive subjectivity of the international working class, and through the development of the automation of large-scale industry within the NIDL, this book advances a substantive explanation of the inner relation between global transformation and uneven development that may well provoke criticism and debate, but which at least does so on distinctive and hitherto largely unfamiliar grounds.

Outline of the Book

The argument in Part I of this book—containing chapters by Iñigo Carerra, Caligaris and Starosta—sustains that Fröbel, Heinrichs, and Kreye were right to proceed from a global perspective on capital accumulation, and also right in the centrality they attributed to the recent material transformations of the capitalist labour process as key to the explanation of the developmental potentialities of late-industrialisation. On the basis of this critical re-examination of the NIDL thesis, the book goes on to argue that a revised NIDL thesis can shed new light on the specificities of capital accumulation in various parts of the contemporary world. Two particularly significant general insights emerge from these early chapters. First, that both the classical and new international divisions of labour should be most fruitfully re-signified in terms of the role played by *ground-rent* in specific national spaces of accumulation (a category explained in Part I). And second, that there remain essential continuities inherent to the classical international division of labour which necessitate that the current constellation of the world economy be understood as being constituted by the co-existence of both old and new international divisions of labour.

Such insights carry with them important and hitherto unacknowledged implications for the study of international political economy, and conclusions that contrast sharply with dominant critical and orthodox theories of global capitalism and uneven development.

The remainder of the book incorporates case study material on four countries in Latin America, two European countries, and one Southeast Asian country. The choice of national case studies in Part II is by no means arbitrary.[5] Each of the countries the respective authors examine is, in their own way, paradigmatic and emblematic of the essential dynamics of the NIDL that we are seeking to draw out theoretically and concretely in this book. Argentina and Brazil, for example, are the most visible examples of countries in which the structural characteristics of the CIDL persist and complement those of the NIDL to this day (certainly since the recent commodity export boom, and the revival of import substitution industrialisation under the Kirchners in Argentina). Ecuador and Venezuela represent the starkest examples of what Thomas Purcell in his chapter terms 'landlord states' within the contemporary international division of labour. And, notwithstanding their 'advanced' country status, Ireland and Spain continue to occupy a position within the NIDL on the basis of the differentiated and relativised development of the productive subjectivity of their working class, and therefore allow us to cast fresh light on the dynamics of development, capital accumulation, and crisis outside of the 'late industrialising' states of Latin America and Southeast Asia. Finally, South Korea stands out as the country which, in the past, has been used to undermine the original NIDL thesis since its 'take-off' is often said to be the exception that disproves the rule of that thesis (as formulated by Fröbel, Heinrichs, and Kreye, of course).

The book begins with a chapter originally published in Spanish, which introduces Juan Iñigo Carrera's take on the NIDL. In it, Iñigo Carrera proceeds from a particular point of departure, that is, from the *global process* of accumulation in its organic unity, and within which distinct national processes of accumulation emerge as specific concrete forms of that same global process. He argues that there is an objective determination relating to the formation of a general rate of profit as the regulator of the unity of the process of capital accumulation, and which engenders a qualitative difference between those capitals that are able to contribute to that formation and those which cannot—resulting therefore in differentiated concrete rates of profit. The latter sections of the chapter integrate these two arguments so as to present an innovative, critical, methodological basis for the re-examination of the CIDL and NIDL—one that sharply contrasts with dominant interpretations.[6]

In Chap. 3, Gastón Caligaris provides fresh insight into the old, or classical, international division of labour and into the development of capitalism in resource-rich countries whose longstanding historical role in the world market has been to produce ground-rent-bearing commodities. The chapter builds, again, upon the notion of capital accumulation as being global in content and national in form. From this perspective Caligaris challenges a dominant perspective that explains the functioning of a national economy as the result of domestic politics, and another that explains it as a consequence of foreign influence and domination. He instead presents an original approach that explains the specific characteristics of the national process of accumulation in countries specialised in the production of ground-rent-bearing commodities, and in doing so substantiates the argument that ground-rent is essentially constituted by the surplus-value resulting from the valorisation of industrial capitals abroad and which flows into 'resource rich', raw materials-producing countries. The chapter therefore further advances the critique of those approaches that attempt to explain such characteristics through theories and analyses of unequal exchange with advanced capitalist countries. The latter sections of the chapter use empirical evidence from the example of capitalist development in Argentina during the twentieth century to illustrate the core argument.

In Chap. 4, Guido Starosta turns his attention to the task of the critical reconstruction of the NIDL thesis. While acknowledging the insights of the original thesis, Starosta argues that the foundation for the emergence of the NIDL does not reside in the intensification of the manufacturing division of labour, that is, in the deskilling resulting from the subdivision of the production process into elements. Instead, the NIDL developed as an expression of the impact that the progress of the automation of capitalist large-scale industry has had on the individual and collective productive subjectivity of the working class. More specifically, the constitution of the NIDL has been the result of the transformation of the modes of existence of the global collective labourer, brought about by the leap forward in the process of computerisation and robotisation of the production processes of large-scale industry, especially since the 'microelectronics revolution'. As a result of its own immanent tendencies, the simplest original form of the NIDL has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class. Each national sphere of accumulation therefore tends to concentrate a certain type of labour-power of distinctive material and moral productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital as a whole in the least costly possible manner. Production in specific industrial sectors has thereby expanded in some countries, while contracting in others where new and more advanced sectors developed, following a rhythm determined by the evolution of those two main factors—i.e. technological change and the relative cost and productive attributes of national labour forces. An important claim made by this chapter, therefore, and which subsequently has relevance for Chaps. 5 and 9, concerns the degree to which structural characteristics of the CIDL and the NIDL today co-exist in national spaces of accumulation—particularly in Latin America. This, the chapter concludes, actually confirms the validity of a reworked NIDL thesis rather than its unequivocal refutation.

Part II turns to national case studies of capitalist development within the international division of labour. In Chap. 5, Thomas Purcell scrutinises the experiences of two countries whose national governments have been said to be representative of 'post-neoliberalism', Ecuador and Venezuela. Taking his cue from Part I, Purcell argues that the CIDL was never simply reducible to the polarisation of an industrialised core and a dependent periphery, with the latter restricted to the role of supplier of raw materials and staple foods. Rather, there was an important process of accumulation in the periphery, whereby national industrial capital was able to valorise through the appropriation of inflows of ground-rent; a process which today also points towards the continuation of elements of the classic within the new IDL. The global rise in primary commodity prices in recent years has put the question of the use of income from natural resources for developmental goals back on the political agenda across Latin America. Drawing upon Iñigo Carrera (2007), Purcell examines the distinction between agricultural and mining landownership in the context of global transformation associated with the international division of labour, so as to explain the developmental trajectories of Ecuador and Venezuela. He argues that dual landlordism in Ecuador—in the form of an agro-export elite and a state-controlled oil sector—contrasts with the singular dominance of the state-controlled oil sector in Venezuela, and this, for Purcell, explains the manner in which the two national forms of insertion into the international division of labour have determined different national variants of post-neoliberalism.

Chapter 6 examines Ireland's rapid structural economic transformation during the 1990s, and the debates that emerged about the potentialities and limits of this idiosyncratic 'developmental model', and its apparently successful integration into the global economy. Whilst neo-liberal economists have tended to explain the Irish experience of rapid growth in terms of the adoption of a liberalisation and export-led strategy that opened the economy to vast inflows of 'high-tech' FDI (foreign direct investment), critical commentators have argued that such an account ignores the active role actually played by the Irish state and related institutions and organisations in shaping the precise mode in which the 'local' economy integrated into 'globalised networks' of high-tech production and innovation. According to this alternative view, the Irish case is actually that of a Network Developmental State that manages the connection between the local and the global and, through its active involvement in industrial development, steers the national economy along a path of integration into the technologically most dynamic elements of the world economy. In contrast to the authoritarian state developmentalism of the East Asian Tigers, and their (initial) reliance on the 'super-exploitation' of cheap manual labour, the Celtic Tiger model would be predicated on democratic institutions and more qualified, higher-wage jobs in cutting-edge sectors of the economy. Tomás Friedenthal and Guido Starosta take issue with these apparently opposed explanations insofar as they both explain the trajectory of the Irish developmental process on the basis of the successful implementation of 'correct' nation-state policies (even if they disagree on the precise nature of those policies). By contrast, this chapter argues that the Irish experience is yet another concrete expression of the further development of the essentially *global* dynamics of the NIDL. More specifically, it argues that the continuous skill-replacing technical change characterising the production of relative surplus-value across the globe has allowed capital to integrate national working classes with more skilled, but still relatively cheaper, labour-power into the NIDL. The peculiar state policies and institutions prevailing in Ireland are therefore grounded in this specific form of integration into the NIDL.

In Chap. 7, Greig Charnock, Thomas Purcell, and Ramon Ribera-Fumaz focus on the case of Spain in support of Iñigo Carrera's argument that, as a result of the general crisis of overproduction, the marked differentiation in the conditions of reproduction and exploitation of the working class *within* national borders since the 1970s has unfolded through a form of differentiated integration in Europe. Charnock, Purcell, and Ribera-Fumaz argue that it is crucially important to understand the longer-term historical role played within the NIDL by relatively late-industrialising countries that are today bearing the brunt of crisis and internal devaluation in a 'unified' Europe. Focusing on Spain, they argue that it is precisely on the material basis of its full integration within the NIDL from the mid-1970s that the conditions of the reproduction of the working class were reshaped, and it is this historical component in the reproduction of the Spanish accumulation process that has prefigured the process of the differentiation of the conditions of the reproduction of the working class across *and* within its borders ever since.

In Part III, we turn to specific sectoral case studies within the NIDL. The choice of case studies is again not arbitrary, since the automotive and steel production sectors have been at the historical vanguard of the move towards the NIDL, and they have been industries in which the actual determinants of the NIDL, which the book seeks to identify, have been most visible. In Chap. 8, Alejandro Fitzsimons and Sebastián Guevara examine the historical development of the Argentine automotive industry from the mid-1950s to the present. They argue first that the peculiar characteristics of low scales of production, obsolete technology, and the resulting low global competitiveness of the local auto industry in its initial stages were determined by the specific form of capital accumulation prevailing in Argentina as a result of its participation in the CIDL. This specificity had at its core the process of appropriation by industrial capital of a portion of the relatively abundant ground-rent available in Argentina; in this case, by transnational automotive manufacturers. Challenging the dominant point of view that the development of the NIDL led to the qualitative restructuring of the Argentinean automotive industry, this chapter examines concrete changes within the labour process and forms of valorisation of capital in the industry. In so doing the chapter argues that, despite these changes, the automotive industry in fact continued its development on the same basis as before—i.e. the appropriation by TNCs of a portion of agrarian ground-rent. Fitzsimons and Guevara conclude, therefore, that the NIDL did not 'restructure' the Argentine automotive industry—as is commonly claimed.

In Chap. 9, Nicolas Grinberg offers an alternative account to the mainstream, institutionalist view on the state-led process of economic development in Brazil and South Korea. Focusing on the development of the Brazilian and Korean steel industries, Grinberg claims that the specific form of participation of each economy in the production of relative surplus-value on a global scale has determined both the pattern of industrialisation that followed, and the political processes through which it came about. In Brazil, industrial capital has accumulated through the state-mediated recovery of ground-rent, which has implied small-scale production for protected domestic markets. By contrast, in South Korea industrial capital has accumulated through the exploitation of a relatively cheap and disciplined workforce performing simplified activities for world market production in increasingly complex sectors. The significance of Grinberg's analysis for us is that, while South Korea's 'take-off' is often used to refute the original NIDL thesis, the Korean case actually vindicates the revised version of the NIDL thesis put forward by this book.

NOTES

1. See, for example, Iñigo Carrera (2006, 2013, 2014, 2015). Several of Iñigo Carrera's other working papers are available in English through the CICP web site: http://www.cicpint.org/CICP%20English/Principal.html.
2. The productive attributes of workers include the strictly material or technical dimension of labour-power required by the particularity and complexity of the productive functions to be performed, as well as its 'moral' attributes (that is, the general forms of consciousness and self-understandings that make those workers suitable for the specific forms of discipline that a certain organisation of the capitalist labour process entails). The term 'productive subjectivity' captures this twofold dimension of labour-power.
3. As Radice (2009: 29) summarises, 'the mechanism through which this unequal distribution of rewards is sustained is, in essence, that of market structure: businesses and zones engaging in core activities have market power based on superior technology, management and access to finance, while those engaging in peripheral activities have only generic resources of cheap land and unskilled labour, the markets for which are highly competitive.'
4. All three of these frameworks/concepts figure in the selection of articles edited by Bruff and Ebenau (2014). See Rioux (2015) for a critical discussion of Trotsky's notion of 'uneven and combined development', and for a thorough critique of the (failed) attempt to come up with 'a social theory of the international' in the work of Justin Rosenberg and others.
5. It ought to be self-evident from the foregoing outline of the approach taken in this book that a focus on country case studies does not imply a crude

methodological nationalism on our part. But to clarify, Part II focuses on countries for two reasons: first, because even if it is a mediating form and not a self-subsistent content, the national form is real and objective, and it is actually by exacerbating national differentiation that the global content of the NIDL unfolds; and it allows us to show that it is impossible to explain national dynamics as if they were autonomous from the global content of accumulation.

6. An appendix to Chap. 2, which we have been unable to reproduce in this book due to space constraints, is available at: https://www.academia.edu/24332230/End_Notes_to_The_general_rate_of_profit_and_its_realisation_in_the_differentiation_of_industrial_capitals_1?auto=download. In it, Iñigo Carrera confronts two crucial problems: first, the asymmetric relation between national economies of markedly distinct structures; and, second, the asymmetric relation between capitals of very distinct accumulation capacities within the same value chain. Until now, the first question has been approached by means of theories of development and underdevelopment, imperialism, unequal exchange, dependency, and so on. Iñigo Carrera asserts that these theories all conceive of national processes of accumulation as being essentially autonomous. The second question of the asymmetric relation within value chains has, until now, been explained by theories of imperfect competition and of monopoly capital. Both theories agree that such asymmetry results from the behaviour of key agents. Therefore both theories erroneously eschew the existence of objective determinations that regulate social production and consumption through the formation of a general rate of profit.

PART I

Capital and the International Division of Labour

CHAPTER 2

The General Rate of Profit and Its Realisation in the Differentiation of Industrial Capitals

Juan Iñigo Carrera

NORMAL INDUSTRIAL CAPITAL

In the capitalist mode of production, the allocation of the total labour power of society into each form of concrete useful labour takes place by means of the formation of a general rate of profit. Through this process, the total capital of society acts as the subject of its own valorisation by determining individual capitals as its aliquot parts. Individual capitals thereby realise the material unity of the movement of the total social capital through their respective privately undertaken actions as sums of value that valorise in equal proportion with respect to their size and turnover time.[1]

This chapter is a translation, adapted by the editors with the permission of the copyright holder, Iñigo Carrera, J. (2013), of 'Capítulo 5: La tasa general de ganancia y su realización en la diferenciación de los capitales industriales', in *El capital: razón histórica, sujeto revolucionario y conciencia*, second edition (Buenos Aires: Imago Mundi). An appendix to this chapter is available at: https://www.academia.edu/24332230/End_Notes_to_The_general_rate_of_profit_and_its_realisation_in_the_differentiation_of_industrial_capitals_1?auto=download.

The active participation of individual industrial capitals in the formation of the general rate of profit is dependent upon their reaching the necessary degree of concentration required (hence scale) to put into action the productivity of labour that determines the value of commodities.[2] The individual capital that has this attribute constitutes the *normal* or average for the sphere in which it acts. The production of relative surplus-value imposes the need to constantly increase the mass of value that must be accumulated for it to function as an autonomous normal individual capital.

The industrial capitals that fall behind in the process of concentration and centralisation cannot continue operating autonomously. They are compelled to become fragments integrated with other industrial capitals, that is, they are transformed into interest-bearing capitals.

Small Industrial Capital

As we have seen, industrial capitals that cannot keep up with the process of concentration and centralisation cannot continue operating autonomously, and are forced to turn themselves into interest-bearing capitals. However, they can postpone this outcome.

The valorisation of capitals smaller than the norm is not ruled by the general rate of profit but by the rate of interest, which is normally lower. And they do not access this lower rate in proportion to their value as independent industrial capitals. Instead, their value is reduced to that of the liquidation of their productive assets, which are now materially useless for the purpose of valorising as normal industrial capital. Therefore they can remain active as autonomous industrial capitals as long as the greater costs they incur for their small scale are compensated for by the lower profit that governs their existence as small capitals. This possibility of subsistence on the part of small industrial capitals constitutes in itself an obstacle to the development of the productive forces of society. Instead of immediately being displaced by those capitals that put into action the greatest productivity of labour, the extension of their individual life specifically obstructs the constant technical revolution imposed by the general determinations of the capitalist mode of production.

The limit to the subsistence of industrial capitals smaller than the norm is ruled by the general development of the productivity of labour. As soon as this development permits normal capitals to bring the price of production below the price corresponding to the rate of interest on the value of liquidation of small capitals, the latter are finally expelled from production. However, the limit to the subsistence of small industrial capitals can be extended further still when small capitalists are, at the same time, their own direct workers. In this case, the subsistence of small capital in production can be extended to the point at which its owner receives the equivalent of the wage that she could obtain as a simple wage-worker. In agricultural production, in particular, this transformation into a wage-worker can involve a change in the place of residence, which pushes the equivalent salary downwards. The limit may be reached therefore at the point in which it is no longer possible to resume the productive cycle covering the replacement of circulating capital with the return from the fixed capital consumed—that is, at the expense of exhausting fixed capital without replacing it.

On the other hand, the rate of interest generally maintains a direct relation to the size of the individual interest-bearing capital; the greater the size of the individual interest-bearing capital, the greater the rate of interest and vice versa. In this way, the limit imposed simply by the relation between the general rate of profit and the rate of interest presents a gradation that is proportional to the size of the small capital. And this gradation accompanies the increasingly widening gap from the condition of normal capital that necessarily befalls the small capital due to its relatively slower pace of concentration—that is, owing to its lower rate of valorisation. Therefore, small capital is that which does not reach a size necessary for it to actively participate in the formation of the general rate of profit from within its specific sector of production. But the range of small capitals extends from those whose difference with respect to the normal capital in their sector is imperceptible in a given moment (they can *appear* big), to others whose owners are clearly on the verge of liquidation and proletarianisation. At the same time, the continuous growth of the productivity of labour in pursuit of renewed relative surplus-value constantly renews the generation of the range of small capitals. While it expels some from the bottom, it incorporates new ones that had existed as normal capitals in their own right, as it continuously raises the individual scale that, in general, is necessary for a small capital to remain active.[3]

Sooner or later, the development of the productivity of labour by normal capitals will make small industrial capitals reach the limit of their existence. In the end, they are transformed into interest-bearing capitals, if there is anything left of them by then. However, before arriving at this point, it may be possible that small capitals expel normal capitals from the sectors in which they participate. This happens as long as their own limit price is located below the price of production. In this case, small capitals defeat normal capitals in competition.

The Release of Surplus-Value by Small Industrial Capitals

The key to the subsistence of small industrial capitals comes down, therefore, to the relation between the price of production and the price that corresponds to the compensation between the small capital's greater cost and its respective lower rate of profit. Yet, it is not necessarily the case that the price regulating the valorisation of small capitals must correspond to the level of the price of production that regulates the valorisation of normal capitals. In effect, the price that autonomously regulates the valorisation of small capitals cannot be located above that of production, but nothing prevents it from standing below the price of production. In this case, the sale of commodities produced by small capitals for less than the price of production but above the price that rules their specific valorisation implies their appropriation of an extraordinary profit. This extraordinary profit does not result from production at an individual price below the social price of production through a greater productivity of labour. On the contrary, it results from the inability of small capitals to set in motion the productivity of labour corresponding, at least, to the determination of the price of production. Therefore, that extraordinary profit necessarily results in competition between small capitals for its appropriation, thus causing an expansion in production. But this tends to bring the price of small capitals' commodities to the level that constitutes the limit for their subsistence. As a consequence, the extraordinary profit in question, necessarily and eventually, escapes them.

In the case of small agrarian capitals, the first destination for the profit they release can be the pockets of the landlords whose land they rent. Small capitalists pay a premium above the rent corresponding to normal capitals. It can also be the case that this difference is reflected in the greater price small capitalists pay to buy land, which thus exceeds the simple capitalisation of future rent discounted at the rate of interest. This latter modality of appropriation makes small capitalists sink deeper still into such a condition, by the deduction that the greater price of land implies on the total money capital they can turn into industrial capital to be applied productively upon the land.[4] When the profit freed by small capitals follows this path—as it is either generated or advanced in a lump sum through the price of land—the commodities they produce are simply sold at the price of production. The rest of industrial capital has neither won nor lost by this, but the freed profit may follow a different path.

When the accumulation of the total social capital has developed the social division of labour between individual capitals to a limited extent, small capitals tend to directly serve the markets of means of subsistence with their products. In this case, the difference between the lower price that rules the valorisation of small capitals and the price of production appears to benefit merely individual consumers. The corresponding portion of the social surplus-value appears to go into the pockets of consumers via the lower price they must pay for their means of subsistence. However, the course of this portion of surplus-value does not end here. When individual consumers are free labourers selling their labour-power, the lower price at which they buy their means of subsistence is reflected in a cheapening of their labour-power. They are still able to consume the same use values required to reproduce themselves, in spite of receiving a lower amount of value as payment. In this way the surplus-value that had been freed by the specific determination of small capitals ends up being appropriated by industrial capitals as a whole, including small ones. This appropriation is realised as an aliquot part of the respective variable capitals. Therefore it becomes, in turn, a specific concrete determination in the formation of the general rate of profit.

As the accumulation of capital develops, commodities go through a succession of sectors specialised in partial stages of their process of production and circulation before arriving at individual consumption. When, in some of these stages, small capitals intervene by selling below the price of production, the portion of surplus-value that, for them, represents an extraordinary profit, continues to escape them. But to arrive at the market of individual consumption, this amount of profit has to continue its course through the circulation of normal capitals that follow small capitals in the chain. That is, the extraordinary profit in question escapes from the small capitals by means of the normal competition they establish between themselves in circulation. But it can only arrive at individual consumption in the form of a commercial price lower than that of production through the competition that normal capitals following in the chain establish between themselves.

In an immediate way, the release of profit by small capitals to normal capitals takes place through the latter buying commodities at the price that governs the normal valorisation of the former, which is to say, at below the price of production. Now, if the normal capitals were to sell their own product at the price of production, they would appropriate the extraordinary profit contained in the lower price of purchase. It therefore appears inevitable that the competition between them for that extraordinary profit would drag the commercial price at which they sell to below the price of production in corresponding proportion. However, this extraordinary profit does not emerge from those normal capitals putting into action a higher productivity of labour than the social average, so that they can therefore sell their commodities below the social price of production but above the individual price of production. The flow of normal capitals directly in pursuit of extraordinary profit would not respond to the possibility of expanding the total production of the sector, expanding the social necessity for the commodity by selling at below the social price of production at the same time, owing to the greater productivity of labour. As the extraordinary profit is borne by each individual commodity purchased, the competition between normal capitals for the extraordinary profit will only be limited by the expansion of each one's individual productive capacity with the intention of absorbing all that is on offer. No normal capital could refrain from competing for the extraordinary profit before reaching this point. But this would result in the expansion of production beyond the point at which the extraordinary profit was eroded—that is, before the market sale price started to fall below the cost of production. Therefore, the immediate competition between normal capitals for the extraordinary profit would result in their rate of profit falling below the normal rate.

The normal capitals of the sector to which flow the profits freed by the small capitals can compete between themselves for this extraordinary profit only by means of that which is common to all sectors of social production; by increasing the productivity of labour so as to be able to sell under the social price of production but above the individual price. But they cannot compete among themselves directly for the appropriation of the profit released by competition between small capitals to which they relate in circulation through the purchase of their commodities, on pain of destroying themselves as simple normal capitals. The greater the centralisation of capital within the sector into which the extraordinary profit flows, the more apparent become the limits to direct competition to appropriate it. Since the said competition cannot develop, the released profit in question cannot pass to the following sector. It remains trapped as an extraordinary profit to be appropriated by the normal capitals that triumph in the simple competition established through the development of the productivity of labour. These capitals buy means of production at below their price of production, and they sell the commodities produced at the price of production.[5]

For the rest of the total social capital, this appropriation of extraordinary profit precludes the possibility of buying labour power at a reduced wage. In effect, its determination no longer includes means of subsistence being sold at below the price of production. But the autonomous organisation of social production does not provide protection against this situation; after all, the normal capitals of all the remaining sectors buy their means of production and labour-power strictly at the price of production. And the same happens with the means of subsistence bought by capitalists for their individual consumption. In the end, the formation of the general rate of profit is realised at a more concrete level by: determining the existence of below-normal industrial capitals that valorise at a lower concrete rate of profit; the existence of normal industrial capitals that valorise consistently at a higher concrete rate of profit; and [the existence] of normal capitals that simply valorise at the general rate of profit.

This is the true content which political economy inverts by explaining the differences in the concrete accumulation capacities by market-forms, under whose asymmetries this differentiation is necessarily realised. On the contrary, we must grasp the necessity of those market forms as modalities through which the equalisation of profit rates is realised in the concrete form of the differentiation of individual capitals based on their size; that is, from their determination as masses of value that bear no qualitative specificity other than a purely quantitative difference.

The Fragmentation of the Productive Subjectivity of the Collective Worker on the Basis of the Subsistence of Small Industrial Capital

When the total social capital needs to intensify the fragmentation of the productive subjectivity of the working class, it uses the differentiation between the individual capitals, discussed above, to realise it.[6] The precariousness in which decomposing industrial capitals find themselves because of their insufficient size makes them particularly well suited to exercising the brutal exploitation of labour-power whose productive subjectivity is being degraded in the manufacturing division of labour and in its condition as an appendage of machinery. In contrast, this same role can be played by the capital that appears in the opposite pole to small capitals; that is, the capital centralised as property of the state. This possibility is predicated on the constitution of those conditions of exploitation as the general norm within the national sphere.[7]

This functional division in the extraction of surplus-value provides normal capitals with the continuous flow of extraordinary profit discussed earlier. At the same time, the acceleration of the process of concentration and centralisation brought about by the transformation of the productive subjectivity of the worker in large-scale industry guarantees to capitals that triumph in that process the renewed flow of small capitals that release the aforementioned profit. A good part of the success of just-in-time production lies in: the development of information and transport systems; the flexibility of production processes; and in the development of systems of quality control based upon the automation of production processes. But the secret of the other part of its success is merely the reduction for normal capitals of immobilised stocks, at the expense of the accumulation of stocks provided by the small capitals which act as their suppliers. That is, thanks to the lower rate of profit that rules their normal valorisation.

For its part, 'outsourcing' consists purely in the multiplication of the sources of extraordinary profit for normal capitals on the basis of introducing independent small capitals for any of those processes of production and circulation that can be handed over. This introduction is facilitated by two conditions: the relative cheapening of production in limited batches, typical of small scale production, thanks to the automation of the processes of adjusting machinery; and by the more acute conditions of exploitation of labour-power typical of small capital, by virtue of differentiation within the working class. Modern outsourcing is no more than the old putting out system in the guise of scientific management.

Capital Specialised in the Development of Technical Innovations

Individual capitals do not immediately aim to produce relative surplus-value. From their point of view, an increase in the productivity of labour above that of their competitors has only one objective. This is to appropriate an extraordinary profit by selling below the social price of production, to realise on the market the output resulting from an increase in productivity, but at above the individual price of production corresponding to this greater productivity. However, the extraordinary profit disappears as soon as the new technique becomes the general modality of production, which tends to determine the social price of production. If this diminution of the price of production takes place in a sector of social production that, directly or indirectly, intervenes in the production of means of subsistence for the workers, it results in a decrease in the value of labour-power and, thus, in the production of relative surplus-value. Therefore, the production of relative surplus-value excludes the existence of a continuous flow of the extraordinary profit in question for the capitals from any sector of social production and, therefore, the continued realisation by these of a rate of profit superior to the social average.

The capitals that set in motion an increased productivity of labour within a sector of social production are not the only ones that can claim the extraordinary profit generated; it can also be claimed by capitals further upstream whose output consists in the novel means of production that is adopted by capitals further downstream. The capitals downstream that purchase the machinery in order to generate an extraordinary profit will be disposed to pay more for them than the price of production, providing the price paid allows them to cheapen the cost of their own commodity to the point of being able to sell it above the individual price of production. That is, capitalists selling machinery that makes possible the production of extraordinary profit are going to participate to a greater or lesser extent in its appropriation, capitalising it in the price of the new machine. In any case, this participation in the extraordinary profit will disappear as the use of this new means of production becomes more general. However, this changes when the objectified form of the general source of increase in the productivity of labour becomes the product of a special sector of social production. That is, when the production of the technical innovation becomes a sector separate from the production of the machinery in which that technical innovation is materialised. Each renewal of the productive cycle in this sector yields a product for which there is demand by virtue of it allowing the appropriation of extraordinary profit by the capitals that use it. In this way, the capital producing this commodity with the power to increase control over the forces of nature, can achieve a continuous flow of extraordinary profit, constantly renewing the basis for its capitalisation through the selling price.

The transformation in the direct subjectivity of the worker in the process of production is manifest therefore in the emergence of capitals that have the potential to accelerate their accumulation by continually receiving a flow of extraordinary profit, since its product is the basis for a permanent renewal of this flow. Far from violating the law of the formation of the general rate of profit, this capacity for accelerated accumulation merely arises from its realisation. Neither direct competition for the flow of permanent extraordinary profit among those capitals that produce the commodity that makes this profit possible, nor its continuous dilution at the hands of competition between the capitals that effectively utilise this commodity as a means of production, hinders the renewal of this flow.

Since the production of relative surplus-value depends upon the sector specialised in the production of the advance in the objectified capacity to control natural forces, the total social capital has a permanent and substantial reason to participate actively in it by means of its general political representative, that is the state. On the one hand, this production must generally be undertaken on a large scale, which is dependent upon a corresponding degree of the concentration of capital. On the other hand, because of its material form, it is a production in which a good part of the applied capital, if not all, can end up being spent without producing any use value. Since it is about increasing conscious control over the labour process, nothing guarantees the success of this process of production. Therefore, embarking on unproductive paths is a normal condition in achieving effective development. That is why a good part of this production must normally be undertaken by the total social capital itself. This means financing private capitals even if they do not obtain results, or taking on production directly through a state system of research and development. At the same time, when sellers and buyers of the innovations find themselves systematically separated by a national border, there takes place a continuous flow of extraordinary profit from the national sphere of the consumer of that innovation to that of the producer. This reinforces the necessity for every national state to directly participate in this production, in representation of its respective national portion of the total social capital.

FROM THE DIFFERENTIATION OF CAPITAL TO THE DIFFERENTIATION OF NATIONAL PROCESSES OF ACCUMULATION

Historically, the global process of accumulation of industrial capital did not start in an immediately worldwide concrete form. On the contrary, it arose as a confluence of various national processes of accumulation struggling to produce within their national sphere the generality of the commodities they consumed. This integrity of social production and consumption that takes place within a domestic sphere gives an individual appearance to each national process of accumulation. They seem to be whole units of social capital, and not national fragments cut out from the total social capital. To the extent that their effective content fits into this appearance, the accumulation of capital in 'classic' countries takes the concrete forms that immediately correspond to its most simple and general determinations. However, this does not contradict the fact that these spheres are still national fragments of the same total social capital, rather than mutually independent social capitals. In their struggle to affirm themselves through their relative independence, these national processes of accumulation clashed in competition, which is how the process of the global accumulation of capital took shape.

The formation of the world market has an immediate manifestation that goes beyond simple competition to sell the same commodity. The reproduction of individual capitals has, as an immediate condition, the general reproduction of their own national sphere of accumulation. In turn, the reproduction of the national working class as an active population *en masse* has, as an immediate condition, the very same general reproduction of the national process of capital accumulation. Therefore, the capitalist class and the working class in every country establish a direct relation which, in turn, places them in an antagonistic relation with the homologous unity between the class of exploiters and the class of exploited of other countries. This direct relation arises as a limit to the direct relation of international solidarity between the national working classes through which the general buying and selling of labour-power at its value necessarily takes concrete form.

The unity of each national process of accumulation is directly manifest by means of the antagonistic relation that these national processes establish with each other in the world market. The individual capitals do not simply compete as themselves in the world market, but as capitals that immediately represent the distinct national processes of accumulation. Competition in the world market, that is the concrete form through which the unity of the organisation of social production in capitalism is realised, is always mediated by the direct relation between the capitalist and working classes delimiting each national sphere. Therefore, the circulation of commodities in the world market is necessarily mediated by the direct relation that the general political representatives of each national fragment of the total social capital establish with each other—which is to say by the direct relation between the respective national states. The competition between individual capitals in the world market therefore takes a first specific form, that is, competition to sell to the capitals of other national spheres, and to avoid having to buy from them, as a means of expanding as much as possible the scale of their respective national processes of accumulation. Except that, of course, this expansion is dependent upon external supply.

Until now, we have considered the relation between 'classic' national processes in which the accumulation of capital is present in its most simple and general form. However, another form of international relations develops out of this relation between 'classic' national processes of accumulation. In addition to the struggle to sell without buying, the capitals of those national processes of accumulation establish a second focus of mutual competition in the world market; namely, the competition for the supply of raw materials from territories historically located beyond their borders. This concerns production processes in which the productivity of labour is particularly subordinated to natural conditions that are not under the control of normal capitals, and these conditions are most favourable—or simply exist—in those territories located outside 'classic' national spheres where accumulation presents itself in its simplest form. At the same time, capitals from the 'classic' spheres look to expand their own foreign market, selling to capitals or simple commodity producers that provide raw materials from those other national spheres. The capitals and commodity producers in the latter territories now have the capacity to buy since they have sold on the same world market.

Further still, to produce capitalistically in the new territories oriented to the supply of raw materials, with a greater productivity of labour to that prevailing in the 'classic' countries, it is necessary to disburse the capital needed for production and circulation. Its application must therefore be realised on a scale that corresponds to the determination of the price of production on the world market. On the one hand, this capital is gradually provided by the expansion of local accumulation in the new territories. But, as with the simple concentration of capital, this is a slow process that can even make it unviable. On the other hand, for the normal capitals from the 'classic' national processes of accumulation that demand the supply of raw materials, their application in these new productive processes constitutes a source of surplus-value as good as any other. Furthermore, this source can even be circumstantially better, so long as it entails rapidly expanding production, if it is possible to exploit the labour-power of the new country on the basis of the direct relations of personal subordination that already prevail there—or that can be imposed upon it.[8] Therefore, the process of the expansion of global capitalism based upon the differentiation of national processes of accumulation is not only characterised by the expansion of the flows of commodity-capital in the world market; it is also characterised by the flow of industrial capitals and of interest-bearing capitals from the 'classic' countries in which accumulation is based upon the general production of commodities to those countries in which accumulation is based upon the production of commodities bearing ground-rent. Of course, there is a corresponding flow in the opposite direction of the profits and interest that capitals appropriate in the latter countries. In particular, given that the scale of accumulation in the latter is specifically restricted to the production of commodities bearing ground-rent, as well as the complementary production processes that are necessary at the local scale so that those commodities can arrive at their destination, surplus-value flows out of the national spheres in question since it is not required to expand accumulation therein.

The incorporation of 'resource rich' territories with the objective of invigorating the 'classic' national processes in which accumulation appears in its general form has a first historical modality: the direct conquest of those new territories on the part of the 'classic' national fragment of the total social capital that is making use of them. It therefore consists in the military subordination of those territories to the jurisdiction of the conquering national state. The development of the world essence of the accumulation of industrial capital therefore takes the concrete political form of the development of the colonial system, of colonialism.

When the concrete history of the new territory prevents direct military occupation, the formation of an independent national sphere of capital accumulation takes the place of colonial domination. But it does so on the condition that the new national sphere does not reach the scale that is necessary to give rise to a process of accumulation immediately based on the production of the generality of commodities. Certainly, national fragments of the total social capital already in operation have no interest in creating new competitors in the world market. Instead, they are only interested in their geographical expansion to the strictly necessary point at which they can access the supply of raw materials produced with a higher productivity of labour, to increase the relative surplus-value that they appropriate in their national sphere of origin. Insofar as they have been engendered as a necessary concrete form of the expansion of the accumulation of capital in 'classic' countries, this second type of national accumulation process lacks from the very beginning the potentiality to become a ‘classic’ country.[9] The total social capital thus imposes, in various characteristic ways, specific limits to the potentiality of these national fragments *vis-à-vis* those in which accumulation takes place on the basis of production on a normal scale of the generality of commodities consumed domestically. For example: through the direct diplomatic and military action of national states from ‘classic’ national spheres of accumulation; through the supply of commodities usually produced with a productivity of labour unachievable on the scale of the new national sphere; and through the external indebtedness of the new territories. It needs to be stressed that, in all cases, these are the concrete forms taken by the realisation of the limited immanent potentialities of the accumulation process in those new national spheres of accumulation, and not its causes, although this is how it is pictured by those who believe that the accumulation of capital is a national process in essence, and not simply in form.

The production of raw materials from the national spheres specifically constituted for this purpose (‘resource rich’ countries) diminishes the value of labour-power exploited directly by industrial capitals that operate in the ‘classic’ national spheres where accumulation includes the production of the generality of commodities. It acts, therefore, as a source of relative surplus-value for these normal industrial capitals. However, this also involves a drain of surplus-value that these industrial capitals extract from the workers they exploit. A part of this goes into the pockets of the landlords who monopolise the differential and absolute natural conditions that permit the exercise of the greater productivity of labour in the production of raw materials in the form of ground-rent. The industrial capitals from which this portion of surplus-value is drained find themselves impeded—in the last instance by the sacrosanct principle of rights over private property—from recuperating the ground-rent appropriated by landlords within their own, respective ‘classic’ national sphere. But those industrial capitals from ‘classic’ countries do not confront the same problem as regards the portion of surplus-value which is appropriated in national spheres specifically delimited to the differential production of raw materials. All this therefore leads to a *new phase* in the global accumulation of capital based upon the differentiation of the national processes of accumulation between those ‘classic’ spheres where capital produces the generality of commodities and those whose unity hinges upon the production of one or more raw materials bearing ground-rent.

Each national fragment of the total social capital delimited by this second type of national sphere has its unity determined by the productive process that gave rise to the appropriation of differential and, eventually, simple monopoly ground-rent.[10] Hence, the general political representative of that national fragment of the total social capital, that is the respective national state, can act directly upon the mass of ground-rent that is appropriated within its country. Above all, it can become the direct owner of the land whose differential natural conditions allow the appropriation of ground rent. Alternatively, it can interrupt the flow of the ground-rent primarily flowing into the pockets of the landowning class through, for example: special export taxes on raw materials; the fixing of internal obligatory prices for these commodities; their production or commercial exchange by the national state itself; or the overvaluation of the national currency.[11]

In a first historical phase, prior to the 1930s, the portion of ground-rent appropriated in these forms had a primary destination. It was used to pay for foreign public debt borrowed at extraordinarily high interest rates to the capitals of the countries from where the ground-rent flowed. Previously, the funds originated by this indebtedness had been completely squandered instead of being used productively to enhance the general accumulation of capital in the country. More specifically, they had been devoted to the free private appropriation of the territory by the landowning class and to the very formation of the national sphere specifically based on the export of raw materials through warfare against similar countries. It was thus evident that those landowners and foreign capitalists who were creditors of the national state were partners in the formation of national processes of capital accumulation and now shared the appropriation of its fruits; that is, of the surplus-value that flowed towards the country in the form of ground-rent. They were joined by the industrial capitals of the same countries from which ground-rent flowed and which were put to work in the local circulation of raw materials.[12] They participated in the appropriation of ground-rent through the charging of higher prices than in their countries of origin and by taking advantage of the overvalued national currency when remitting abroad the profits obtained internally.

Through interest-bearing capital and the industrial capitals that operated specifically in the circulation of raw materials, the national processes of capital accumulation from where the surplus-value escaped in the form of ground-rent recovered as much of it as possible. However, in a second historical phase, clearly visible after the crisis of the 1930s, this recovery went directly into the hands of the industrial capitals from which the surplus-value in question had escaped.

In order for the ground-rent captured by the direct action of the national state to continue its return to the industrial capitals from which it was drained, these capitals must open and close their valorisation cycle within the national sphere of 'resource rich' countries. Therefore, this national sphere of accumulation has to exclude the possibility of industrial capitals initiating their cycle outside of it and selling their commodities within it. It must constitute itself, therefore, as a national sphere essentially closed to the import of commodities in general, to the extent that the appropriable ground-rent allows for their local production.[13] But, in so doing, this national sphere rules out the valorisation of capitals that locally produce commodities in general on the scale necessary to compete on the world market. It would appear, therefore, that ground-rent can only be appropriated by industrial capitals of insufficient scale to participate in the formation of the general rate of profit, which is to say, by capitals of less than normal or average concentration with respect to their sector of industry, that is, by small capitals. Meanwhile, industrial capitals from which surplus-value has been drained in the first place cannot meet either of the two conditions required for participating in its appropriation within the closed-off national sphere. In the first place, they do not open and close their cycle within the national sphere where the appropriation takes place. Second, their scale generally corresponds to the average necessary to participate in the formation of the general rate of profit in the world market, as they are the most concentrated capitals in the world.

Certainly, a first striking feature of a process of accumulation structured by the general production of commodities for a closed domestic market on the basis of the appropriation of ground-rent is the proliferation of small local industrial capitals. The said appropriation takes place through: the allocation of ground-rent in the form of direct subsidies; the buying of commodities by the national state at prices higher than those of production; public spending that creates the purchasing power to buy the production of small capitals and which, at the same time, generates a deficit financed by monetary issue that, in turn, results in a negative real interest rate at which those small capitals are indebted; and so on.

However, the expansion of small industrial capitals is but the first necessary requirement to generate the bases that make it possible for 'foreign' *normal* industrial capital to become the key beneficiary of ground-rent, in association with the local landowning class. This capital must detach from itself a *fragment* of insufficient scale to produce competitively on the world market, but which is sufficient to function as the most concentrated industrial capital that operates within the national sphere where the ground-rent is appropriated, given the size of this domestic market. This marks a significant difference from the previous historical period. In that earlier phase, the detachment of fragments of normal capitals from their country of origin to be able to valorise in new ones was dependent upon these fragments maintaining the attribute of being normal capitals, which is to say, that they had sufficient scale to produce for the world market. By contrast, in the new phase the detaching fragment of normal capital need only reach the restricted scale corresponding to the closed-off internal market of the national process of accumulation in which it is going to valorise.[14] In restricting itself in such a way, it becomes incapable of competing on the world market. The specific restricted scale with which this fragment of capital operates deprives it of the capacity to valorise at the general rate of profit. In part, this deprivation is to be compensated for by the most acute concrete conditions in which the exploitation of local labour-power takes place. But, above all, this deprivation is to be compensated—if not more than compensated—for by the appropriation of two sources of surplus-value now available to it by virtue of opening and closing its cycle within the national sphere in question: on the one hand, the ground-rent whose appropriation by industrial capital is mediated by the direct regulation of the national state; and, on the other, the surplus-value that is released in the competition between genuine small industrial capitals that link themselves to the fragment of normal capital in internal circulation.

In this way, normal capital valorises at the general rate of profit (and even at a higher rate of profit) by detaching from itself a fragment of a specifically restricted magnitude. Thus, it accumulates by doing the precise opposite of its general need to constantly expand the scope of the conscious control of social labour under its private command.[15] At the same time, it recuperates from the scrapheap the means of production (machinery, patents, and so on) now deemed obsolete by the growth in scale required to compete in the world market, but which appear as cutting-edge at the scale of the closed-off internal market in which they are now put to work. Normal industrial capital that valorises in this way is liberated, in corresponding proportion, from its historical generic necessity to develop the productive forces of society on the basis of constantly advancing the transformation of individual free labour into an immediately social power.

This mode of appropriation by industrial capital of the surplus-value that originally escaped from its hands in the form of ground-rent, necessarily takes the concrete form of an internal market closed to any normal capital from the world market—unless that capital detaches from itself a fragment of a specifically limited magnitude that will valorise as an industrial capital only *within* the national sphere in question. This is a condition that normal capitals need to impose *upon themselves* in order to realise this mode of appropriation. If this were not the case, normal capitals that produce from abroad and which, therefore, maintain an appropriate scale corresponding to the supply for the world market would wipe the floor with the fragments of normal capital that operate on a scale specifically adequate to the restricted scale of the internal market. But, at the same time, this fragmentation is a necessary moment in the generation of the modalities of the appropriation of ground-rent. Thus the fragments of specifically restricted scale from the most concentrated capitals of the world are the first to clamour for the protection of the national state of the country in which they have installed themselves, arguing their case as incipient industrial capitals in a struggle to consolidate themselves in the face of foreign competition.

The relative enclosure of the national sphere of accumulation presupposes the political autonomy of the national state. This national modality of accumulation clashes, therefore, with the colonial organisation of the supply of raw materials and the formation of markets for direct export from the 'classic' countries where accumulation takes simplest form. For the same reason, the specifically restricted fragments that are detached from normal capitals need to be politically represented in another specific way. That is, they need to be represented by their own national state, through its relation with the formally autonomous national state where the fragments are going to valorise. As the existence of this second state is but the concrete form of realising a particular aspect of the process of accumulation of the portion of the total social capital politically represented by the first, there is no doubt as to which of the two states is to have more political and military force when they are confronted formally as equals in an international relationship.

However, within its own national sphere, the local state plays a much more prominent role. Its actions take place at the very centre of the process of the appropriation of ground-rent. It becomes, therefore, the political subject that appears to create through its direct action a national process of capital accumulation that, according to the magnitude and form of the ground-rent it has at its disposal, more or less resembles one in which industrial capital tends to produce the generality of the commodities consumed in the domestic market. The state's own apparatus thus *appears*, in an inverted fashion, as the social subject capable not only of politically representing in a general manner the national process of accumulation, but also of engendering this process by itself. In this way, the fragments of normal capital manage to be represented internationally not only by their own national state of origin, but also by their local political representation exercised through the state apparatus from the country in which they are operating. However, this national process of accumulation must necessarily take the concrete form of an autonomous political process. As a consequence, the constitution of the national state can only result from the action of the local social classes.

The first social class that acts directly for the formation of an autonomous national state is that of the local landowners, who will begin to appropriate ground-rent as soon as land is put into production. The national petty bourgeoisie also acts, in association with the former, in the formation of the autonomous national state, even if this association appears in the form of a fight to the death over the appropriation of rent. This petty bourgeoisie engenders itself as the owner of the mass of small capitals that will constitute the basis for the later entrance of the restricted fragments of normal capital from abroad. In turn, the expansion of small capital, whether genuine or the particularly limited fragment of normal capital, engenders the national working class. This national working class may have originated in the transformation of the traditional local peasants, or it may have had its genesis in the import of workers from other countries. But, in any case, it ends up being peculiarly determined by the very specificity of the national process of accumulation. However much this national working class confronts the local petty bourgeoisie and the local representatives of the fragments of normal capital in the struggle over buying and selling labour-power at its value, it finds that its own immediate reproduction as an active working class is subject to the reproduction of the national process of capital accumulation. Thus it is subject to the reproduction of the specificity of that process. Therefore, the political party that embodies the general representation of the national working class acts as a specific political representative of this reproduction. Without going further here, it becomes an immediate necessity for this political party to associate with the two aforementioned personifications of the industrial capital operating locally in the struggle against landowners over the appropriation of ground-rent. This political party faces the same situation with respect to the confrontation that the same capital sustains against the normal capitals that operate in the world market as simple exporters of the generality of commodities. The general political representation of this type of national process of capital accumulation thus assumes its most characteristic ideological expression, that is populism (as a class alliance that acts on behalf of the national interests of the people).

The national process of accumulation into which ground-rent has primarily flowed, has failed to convert this mass of social wealth into industrial capital concentrated on a sufficient scale so as to *actively* participate in the development of the productive forces of society. On the contrary, only small capitals and specifically restricted fragments of normal capitals operate within it—that is, two forms of industrial capital whose existence is the negation of that development and, therefore, the negation of the historical *raison d'être* of the capitalist mode of production. At the same time, upon being tied in a specific manner to the generation and immediate reproduction of those two forms of capital, the national working class is deprived of the potential to revolutionise the material conditions of the social process of production. Therefore, it is deprived of the generic power of the working class to revolutionise the very mode of production.

However, all these negations and deprivations remain hidden, and appear inverted, when the analysis stops at the appearance that capital accumulation is above all a process of national nature. From this point of view, capital accumulation cannot be recognised as a process whose unity is *determined* by its global essence, and that is *realised* in the concrete form of mutually independent national processes. It thus appears that all national processes of capital accumulation have, in essence, the potentiality to include the production of the generality of commodities putting into action the productivity of labour corresponding to the valorisation of the capital that bears the development of the productive forces of society. The clear evidence that the national processes of capital accumulation in question are lacking in this potentiality is inverted as the expression of their insufficient development; insufficient development that, accordingly, appears as nothing but a mere stage in the natural course of every process of capital accumulation towards the realisation of its national essence. The negation of the development of the productive forces of society is thus represented, in an inverted fashion, as the affirmation of a national process of capital accumulation on its 'path to development'. If this process does not fully travel down the path to 'full development' as an autonomous national process of accumulation, the matter is solved by claiming that such a circumstance can only be due to the application of 'incorrect' economic policies or the presence of some internal 'deformity' or 'perverse behaviour'; for example, the lack of 'capitalist' behaviour on the part of landowners.

In contrast to this open apology of a form of capital accumulation that negates its generic necessity to develop the social forces of production, 'anti-imperialism' appears at first sight to be its uncompromising critique. However, this critique is also based on the *appearance* that capital accumulation is, in essence, a national process. Therefore, it attributes to capital a potentiality that it not only lacks, but which is also the opposite to that which truly corresponds to its existence in the concrete form that it takes in the, allegedly, 'underdeveloped' or 'oppressed' national spheres in question. The potentiality that these latter lack is precisely manifest in the fact that national industrial capital, except for the part that bears the ground-rent, is not able to close its turnover cycle by selling in the world market. Such impotence comes from the insufficiency of the productivity of labour that capital puts into action in those national spheres, owing to the insufficiency of its scale in relation to that determined by the formation of the general rate of profit in the global unity of accumulation. Yet, once the national fragment of accumulation is considered as its natural unity, the norm corresponding to capital accumulation's global essence appears ideologically inverted; it is not that the national fragment of the total social capital has an insufficient degree of concentration, but that those they confront in the world market have an abnormally excessive concentration—an inversion that can only be completed by reducing all essential differences in the capacity for accumulation of one or other capitals to their manifestation in circulation and to the political and military forms they take.

The specific limitations that prevent the expansion of the scale of these national processes of capital accumulation, and that arise from the fact that they are based upon the negation of the development of the productive forces of society, are in this way inverted as an external circumstance on a double basis. On the one hand, the power exerted by capitals that reach the normal level of concentration required to sell in the world market, which derives from their being bearers of the development of the productive forces of society, *vis-à-vis* the restricted power of those that subsist against the grain of that tendency, becomes ideologically represented as the exercise of an abstract 'monopolistic' character. On the other hand, the consequent differential power of the respective national state as the political representative of a national accumulation process bearing in its unity the development of the social productive forces over a state that politically represents a specific negation of this development, is ideologically conceived as the exercise of an abstract 'imperialist' character. In summary, the affirmation of the political autonomy of the national accumulation process as a condition for the appropriation of ground-rent by normal capitals that operate as such in their own countries, which partially liberates these capitals from their generic necessity to develop the productive forces of society, is conceived ideologically as an inverted process of 'national liberation' against 'monopolistic imperialism'.

The general growth in the concentration and centralisation of capital has a double effect on the reproduction of the specificity of these national processes of accumulation. On the one hand, it continually widens the gap between the productivity of labour that must be put into action to compete on the world market, and that which is sufficient for the specifically restricted magnitude of the national market. As a result, the reproduction of the national process of accumulation in 'resource rich' countries is dependent upon the availability of an ever-increasing mass of ground-rent so as to compensate for any productivity gap. On the other hand, the growth in the concentration and centralisation of capital in the relative terms that apply within the national sphere necessarily takes a specific form. It consists in the expropriation and liquidation of simple small capitals at the hands of the particularly restricted fragments of normal capital that operate within the country. This expropriation does away with the surplus-value that is released by those small capitals, and which constitutes one of the sources that enable the fragmentation of normal capital to operate at the restricted scale of the internal market. At the same time, this multiplies the mass of fragments of normal capital whose valorisation is specifically based upon the appropriation of ground rent and of the surplus-value released by small capitals. As soon as the ground-rent ceases to grow rapidly enough to compensate for the widening gap in the productivity of labour and the absolute and relative reduction of the surplus-value released by small capitals, the national process of capital accumulation reaches the specific limit to its reproduction. It enters into a contraction of scale, which can be merely relative with respect to the global pace of accumulation, or directly absolute. As a consequence, the reproduction of the national process of accumulation loses its original condition of being the specific basis for the expansion of the local demand for labour-power and turns into a correspondingly specific source of surplus labouring population in the process of consolidating itself in such a condition.[16] Before, this national process of capital accumulation mimicked that based upon the production of the generality of commodities for the world market, and, therefore, a process of development of the material productive forces of society. Now, its true content against the grain of such developments, and, therefore, as a source of multiplied misery and suffering for the working class, has become immediately manifest.[17]

The development of capital accumulation on the basis of the production of relative surplus-value has yet another effect on the specificity of national spheres. It massively transforms those peasant populations settled outside the countries in which they take the simplest form into a surplus labouring population. In part, capital produces this surplus population in such a magnitude that it no longer necessarily requires a proportion as an industrial reserve army. This population is consolidated as a surplus to such an extent that it is deprived of any potential productive subjectivity. When not reduced to this desperate condition, capital converts the peasant mass into a working population from which emerges the labour-power whose productive subjectivity consists in functioning as an appendage of machinery in the modern division of labour. Thus, it is generated as a latent surplus labouring population until the development of automation allows for the fragmentation, in an ostensible manner, of the reproduction of workers bearing the two types of productive subjectivity typical of large-scale industry.[18] Then, capital effectively puts this degraded productive subjectivity into action on the basis of the specific differentiation of its reproduction with respect to that portion of the working class which is a direct bearer of the development of the productivity of labour through an advance in the objectified control of natural forces.

Whether it is a consolidated surplus population, a latent one, or a labouring population that remains active on the basis of the degradation of its productive subjectivity, capital needs to remove all direct relations between all three segments of the working class and the portion bearing the productive subjectivity that advances in the control of the forces of nature. Furthermore, it needs to eradicate all direct relations between those three forms of existence of the global working class and the organ of the collective labourer of degraded productive subjectivity, which is simply a relative surplus population *vis-à-vis* the needs of the accumulation process, but which must remain localised in direct contact with the bearer of the developing productive subjectivity. Any direct relation that the first portions of the labouring population maintain with the second constitutes an obstacle to the differentiation of their conditions of reproduction.

Capital cannot liberate itself from reproducing the second upon the basis of the conditions that correspond to the reproduction of labour-power bearing the most developed productive attributes.

The direct relation that clashes most starkly with the differentiation in the conditions of reproduction of the working class, according to the distinct types of productive subjectivity, is that of the citizenship of the same national state. The colonial system establishes a direct citizenship relation that unites the two portions of the working class, no matter how asymmetric this relation might be. When entire territories move towards the condition of reservoirs of surplus population, the national fragments of the total social capital from 'classic' countries lose all interest in keeping political control over these territories. Furthermore, this occurs when the development of the general phase of relatively undifferentiated production of labour-power in activity is still in full swing.[19] The colonial system thus loses the last basis of its existence. Not accidentally, this is the moment when 'every man for himself' replaces the alleged 'commonwealth'. The colonialist states therefore sharpen their direct oppression of the population and the economy of the colonies until achieving political independence becomes a condition for the immediate reproduction of human life within them, even as a surplus population. The hour of triumphant anti-colonialist revolutions has arrived.

The capitalist apology based upon the inversion of the global unity of capital accumulation as an inherent attribute of every national process returns to the scene. From this point of view, the determination of the population of the new national spheres as a surplus labouring population stripped of its productive subjectivity by the growth of capital accumulation, appears as the consequence of an insufficient development of capital accumulation in these new national spheres. The very result of the full global development of capital is thus represented as its opposite, as a product of national 'under-development'. This apology has its correspondence in the critique based upon the same inversion. The more capital manages to feed accumulation on the basis of differentiating the reproduction of labour-power according to the productive attributes that it demands from each one of the fragments of the working class, the more it is liberated from its generic necessity to produce wage-workers bearing a universal productive subjectivity. Consequently more capital accumulates, in spite of moving against its generic historical necessity to develop the productive forces of society. However, the critique based upon the appearance of the national essence of accumulation sees an inverted content in the concrete political forms taken by the process in which capital is liberated from its own historical necessity. According to this critique, this consists in the defeat of 'imperialism' exercised by national states of 'monopolistic' capital at the hands of the processes of 'national liberation' of the 'oppressed peoples'.

NOTES

1. *Editors' note*: In accordance with the Marxian notion of capital-as-process, and of the concentration of capitals, Iñigo Carrera uses the Spanish word *monto* (amount or discrete magnitude), which we translate throughout this chapter as size.
2. This determination of industrial capitals formally extends to commercial capitals. These do not produce surplus-value, but, on the contrary, are themselves an unproductive expenditure of surplus-value. Commercial capitals whose scale permits the minimum unproductive expenditure of surplus-value necessary for their realisation participate in the distribution of the total surplus-value produced by the productive workers of industrial capitals. For greater clarity, the exposition only makes reference to industrial capitals. But, *mutatis mutandi*, the reasoning also applies in a formal manner to commercial capitals.
3. However large may be the scale of concentration required for an individual capital in a sector of social production to put into action the productivity of labour that corresponds to the determination of the value of the respective commodities produced, and even if to reach this concentration in a sector the same industrial capital needs to extend over several sectors, this degree of concentration is the one that defines normal capital. This is, therefore, the proper scale of individual capital without qualifications. The category of 'big capital' applied to normal capital does nothing but reflect the point of view of the ideological representatives of small capital, that is, the one that has particular restrictions in its capacity for self-valorisation due to its insufficient size. The purpose of this category is to give normal capital and small capital equal status so as to make them appear as simple species of a same genus, only differentiated by the power that seems to abstractly emanate from their magnitude. This is intended to hide the fact that, whereas the former bears in its increasing concentration the development of the material productive forces of society in the capitalist mode of production, the subsistence of the latter is an expression of the hindrance to that development raised by this same mode of production. Lenin uses the expression 'big capital' uncritically (Lenin 1964: Chap. 2) precisely from the economists of his time, who expressed the mentioned conception about the scale of concentration that was being reached by normal capital

at that moment. Lately, this category has been repeatedly used as if it contained in itself the revolutionary critique of the capitalist mode of production.

4. It is apropos of the determinations of ground rent with regard to small industrial capital applied to agrarian production that Marx, in *Capital*, leaves open the question of the specificity of the valorisation of small industrial capitals (Marx 1981: 938ff). And it was reasonable that Marx did not elaborate since—in contrast to the beliefs of those who put the differences in the concrete capacities of accumulation at the core of their analysis of the general historical development of the capitalist mode of production (resorting to the categories of monopolistic capital, big capital, and so on)—this differentiation is irrelevant for that development. It only relates to the concrete forms of competition. This, of course, is far from saying that it must be explained through the forms of the market.
5. We consider here only the simplest form of the flow of profit released by small capitals of one sector to normal capitals of another, in which the commodities sold by the former to the latter act as the vehicle. However, *mutatis mutandi*, the same determinations are valid for the inverse path, in which normal capitals of one sector sell their commodities at above the price of production, in the proportion required, to the small capitals of another sector.
6. *Editors' note* (see Chap. 4).
7. *Editors' note*: as is the case, for instance, for state-owned companies in contemporary China.
8. The capitalist mode of production is but the necessary historical form in which society develops its productive forces on the specific basis of transforming the productive powers of free individual labour into productive powers of free collective labour, in the concrete form of being the very negation of social labour, that is, as private labour. Therefore capital removes all forms of labour organised on the basis of relations of personal dependence, whether of a coercive nature or not. It needs to impose everywhere the labour of the doubly free workers, as in the sense of not being subordinated to any relation of personal domination, as well as being separated from the means needed to reproduce their life by working individually. That is to say, it needs to impose forced labour everywhere, not through direct coercion upon the workers, but based on their very condition as free individuals. Nonetheless, due to its immanent contradiction consisting in socialising free labour as an attribute of private labour, that is, of the very negation of the immediately social character of free labour, capital does not give up any chance to multiply its valorisation by acting against its own *raison d'être* as a specific historical form of the development of the productive forces of society. Hence, whenever the immediate multi-

plication of relative surplus-value by means of advancing the private socialisation of free labour is not at stake, it becomes the champion of forced labour through direct coercion against the worker. Agriculture and mining provide a twofold specific basis for this. Firstly, the submission of the productive power of labour to natural conditions not controlled by normal capital is a limit to the development of the technical composition of capital. Therefore, the productive attributes of free labour take longer to express their specific potentiality compared to industrial production in general. Secondly, the subsistence of relations of personal subordination that are the foundation upon which the direct coercion exercised by capital is based, presupposes the direct attachment of the worker to an essential means of production, namely, land. This circumstance has created the inverted appearance that social processes of production ruled by the production of capitalist commodities for the world market are but the expression of the subsistence of feudal or slavery relations prevailing over the valorisation of capital. An inversion from which it follows that the revolutionary path, in those cases, means engendering a national bourgeoisie that could establish locally the capitalist mode of production upon the remnants of feudalism and slavery. The more capital moves forward in its necessity to count upon a universal worker, the greater difficulty it finds in sustaining its valorisation in particular sectors of social production on the basis of the subsistence of directly forced labour. A clear example in this sense is the clash between industrial capital from the north of the USA with agrarian capital in the south over the abolition of slavery. But, at the same time, capital always keeps latent the choice for forced labour if it can be obtained with the productive attributes of free labour. The Nazi concentration camps are a brutal manifestation of this. In them, a portion of the total social capital lives the dream of any individual capital: counting upon an originally free labour-power without having to spend a penny even in its daily reproduction, as it could rely on a continuous flow of it and eliminate any individual immediately unable to work.

9. The exceptions to this determination can be counted, at most, on the fingers of one hand. But the case of the USA constitutes an absolute singularity. This is not the place to discuss this thoroughly. Nevertheless, we can quickly point out that this singularity synthesises several determinations. To begin with, the very emergence of the colony does not hinge on the production of precious metals used for circulation as world money based on indigenous labour-power. Nor does it hinge on providing forced workers for employment in other regions. On the contrary, it is engendered by British capital—in what matters for its future singularity—to satisfy the need to expand its own domestic market. And it does so by annihilating the indigenous population that organised its reproduction through direct per-

sonal relations. On this basis, it then occupies the territory with the surplus population generated by the development of its primitive accumulation and, afterwards, by the expansion of industrial capital in England and Europe. Hence, land ownership is fragmented among the settlers, in contrast with its concentration in the new territories devoted to the production of raw materials under the plantation system or to the breeding of livestock in natural plains. This contrast is also valid in relation to the south of the USA, a region that does not play a direct role in the determination of the singularity in question. Besides, the expansion of the domestic market could reproduce itself on the same basis by extending to the west, and on a scale greater than that possible in similar European national spheres. The formation of an independent national sphere on such a scale already implies a singular potentiality. But, additionally, the USA possessed within its own territory the two natural bases upon which large-scale industry historically developed: iron and coal.

10. *Editors' note*: hereafter, all reference to the appropriation of ground-rent refers to these two types of ground-rent (See Note 3 in Chap. 3, for a definition of the different types of ground-rent.).
11. *Editors' note* (see Chap. 3).
12. *Editors' note*: for example, through the construction and operation of the railway system.
13. *Editors' note*: Since ground-rent acts as the essential source of compensation for the higher production costs that result from the small size of the protected domestic market, the potentiality for the 'inward-looking' production of non-primary commodities depends on the magnitude of ground-rent flowing into the respective country.
14. *Editors' note*: here, Iñigo Carrera is mainly referring to foreign direct investment by transnational corporations since the mid-1950s in, for instance, Latin America.
15. *Editors' note*: in other words, it accumulates against its general tendency to strive to be at the vanguard of the development of the productive powers of social labour.
16. *Editors' note*: this has been the general course of capital accumulation in the southern cone of Latin America since the mid-1970s, and which underlies both its neoliberal and more recent neopopulist political and ideological forms (see Iñigo Carrera 2006; Grinberg and Starosta 2014).
17. Because of the material characteristics of agrarian production bearing rent, and the size and complexity reached by the national process of accumulation based on it, Argentina is the richest concrete case for the study of this specific national modality of accumulation (see Iñigo Carrera 1999, 2000, 2004, 2006, 2007).

18. *Editors' note*: Iñigo Carrera is here referring, on the one hand, to the expanded subjectivity of the organ of the collective labourer responsible for the more complex phases of the labour process consisting in advancing the conscious control of the movement of natural forces (that is, science) and its technological applications in the direct production process and, on the other, to the degraded productive subjectivity of direct production workers that confronts those productive powers as already objectified in the system of machinery (see Chap. 4).
19. *Editors' note*: Iñigo Carrera is here referring to the, so-called, Fordist or Keynesian historical cycle of accumulation and the Welfare State.

CHAPTER 3

The Global Accumulation of Capital and Ground-Rent in 'Resource Rich' Countries

Gastón Caligaris

Drawing upon Iñigo Carrera's (2006, 2007) research on capital accumulation in Argentina, this chapter offers a general explanation of the particular characteristics adopted by national processes of capital accumulation whose main role is to supply ground-rent bearing commodities to the world market. The chapter adopts a methodological approach that recognises the concrete manifestations that such countries present as developed forms of the essential determination of *capital*—capital being the immediate subject of the organisation of the process of social life. Therefore, the chapter begins with an analysis that recovers the Marxian conception of the process of capital accumulation as being global in content and national in form. A perspective that, I argue, strongly contrasts as much with positions that explain the functioning of a national economy as a result of local class struggles, as with those which explain it as a result of foreign impositions within the national sphere. On the basis of the identification of 'resource rich' countries as being organs of the global

process of capital accumulation, the chapter goes on to review some basic Marxian arguments about ground-rent that permit the identification of specific contradictions in the international economic relations established by such countries. On this point, the chapter brings to light a contrasting argument to those of a 'dependency' or 'world systems' perspective that explain this type of national economy on the basis of the existence of some kind of unequal exchange in their trading relations with other countries. Given that the concrete forms in which these contradictions are developed are mediated precisely through the national form of the process of capital accumulation, the chapter ends by examining the specificity of resource rich countries on the basis of the Argentine case.

The Global Accumulation of Capital and the Classical International Division of Labour: The 'Global Content' and 'National Form' of Capital Accumulation

The Global Content and the National Form of Capital Accumulation as Bases for the Explanation of the Specificity of 'Resource Rich' Countries

As is widely accepted by contemporary Marxist scholarship, Marx did not develop his critique of political economy by making generalisations based upon the particular characteristics of one national sphere but by departing from the capitalist system as the form of the organisation of social life (Pradella 2013). Consequently, in order to give an account of the particular characteristics of countries specialised in the production of raw materials, we have to systematically develop the determinations specific to such countries as concrete forms of the existence of (global) capital.

The plan that Marx had outlined for the exposition of the critique of political economy culminated, at least in his most ambitious versions, with a book on the 'World Market' (Marx 1981: 205, 1983: 270, 1987: 261, 1993: 108). Thus, from an early stage Marx considered capitalism to be a universal mode of production and, consequently, of a necessarily global character (Marx and Engels 1975: 49, 1992: 340–1). In this way the world market became for Marx the only place 'in which production is posited as a totality together with all its moments' (Marx 1993: 227), that is, the place where the total social capital (*gesellschaftliche Kapitals*) fully affirms itself as the alienated subject of social production.[1] From this point of view, the 'individual countries' that are 'integral parts' of the 'world market' (Marx 1976: 702) are but aliquot parts of the total social capital, or rather, the particular forms it takes. It follows that the specifically capitalist character of the constitution of national states presupposes 'the establishment of Modern Industry and of the world market' (Marx and Engels 1976: 486), that is, it already presupposes the fully developed global essence of the capitalist mode of production. Considered thus, the process of the accumulation of capital, that is to say the movement of the total social capital as the immediate subject of the organisation of social life, can be defined—paraphrasing Marx—as a process which is global in substance or content, and national only in form (Marx and Engels 1976: 495).

Although this summary goes without saying for many Marx scholars, as some authors have recently noted (Iñigo Carrera 2013: 168 ff; Grinberg and Starosta 2014; Guevara 2011), precisely the opposite conception forms the basis of the great majority of 'Marxist' explanations of the relations established between distinct national spaces. In effect, each time the particular course adopted by the national accumulation of capital is explained as a result of local class struggle and/or impositions from another national sphere—to name the most common explanations among Marxists—it is presumed that each national sphere of accumulation is autonomously constituted and that the relation between them is established on the basis of this same autonomous constitution. Therefore, the global process of the accumulation of capital and its corresponding national differentiation does not emerge out of the immanent necessity of the movement of the total social capital but, conversely, emerges from the interaction between abstractly autonomous national processes of capital accumulation. However, from our point of view it follows that, if the process of capital accumulation is global in content and national in form, the course followed by each national sphere of the accumulation of capital and, therefore, by the national class struggle, has to be explained by the role the national sphere plays in the global unity of capital accumulation, whose synthesis is the world market (Grinberg and Starosta 2014: 240).

According to Wallerstein (1991: 590), in a 'careful reading' of the texts where Marx himself analyses the class struggle at the national level, 'Marx repeatedly explains the different concrete political actions of the British and French bourgeoisies by the fact that they played different roles in the world market'. Although the degree to which Marx fully developed a systematic explanation of the class struggle in a particular national sphere can be debated (Engels 1990: 506–7), and notwithstanding how ‘repeatedly’ an ‘explanation’ can be found in Marx, as Wallerstein suggests, it is certainly possible to find in those texts the ‘repeated’ observation about the need to explain national class struggle through the role the corresponding national sphere occupies in the world market. For example, in *The Class Struggle in France*, when discussing approaches that abstract from the global determination of national class struggles, Marx argues: ‘But French relations of production are conditioned (*bedingt*) by the foreign trade of France, by her position on the world market and the laws thereof’ (Marx 1978: 56).

From this point of view, class struggles and corresponding state policies are, therefore, the concrete forms that mediate the unity of the movement of the total social capital. As is acknowledged by various contemporary Marxist contributions, national states are political representatives of the total social capital (Clarke 1991; Holloway and Picciotto 1978). But since the total social capital is global in content and national in form, national states only represent total social capital through the representation of *national* total social capitals.[2] That is, in the same way as individual capitals behave as aliquot parts of the total social capital, national total social capitals behave as aliquot parts of the global total social capital. The determination of national states as political representatives of national total social capitals is nothing more, then, than the mediated determination of national states as political representatives of global total social capital. In the Marxist literature on the state, this point of view is captured by Clarke (2001: 79) in the following way:

> Although the modern nation-state is constituted politically on a national basis, its class character is not defined in national terms … [T]he subordination of the state to the rule of money and the law, which is the foundation of the constitutional form of the capitalist state, confines the state within limits imposed by the contradictory form of the accumulation of capital on a world scale. Consequently the national form of the capitalist state can be defined only as a condensation, or nodal point, of an international state system.

The course of the national sphere of the accumulation of capital can be explained neither by national political relations nor by the direct relations that are established between distinct national states—that is, their ‘international relations’. As with all the direct relations of the capitalist mode of production, international political relations are but the concrete form in which indirect relations are realised, in this case, international economic relations, which are relations of competition established by individual capitals in the world market. Therefore, as with the political relations that are established within the national sphere, international political relations are mediated forms through which the global unity of capital accumulation is realised (Iñigo Carrera 2013: 145). As a consequence, it cannot be the basis of the explanation of the course adopted by a national process of capital accumulation. On the contrary, it is precisely this course, determined by the movement of the total global social capital, which explains the political relation that the national state establishes with other states.

In summary, this point of view contrasts strongly as much with interpretations that explain the form and the course adopted by a national economy through national political relations [perhaps the most common position in Marxist analysis, whose origin can be retraced to Engels (1990)], as with those that explain it through international political relations [a traditional position which goes back at least to Lenin (1964)]. Finally, it also contrasts with approaches that postulate a simultaneous determination of both national and international political relations [a similarly common and longstanding position that in recent decades has found a certain systematisation in Neo-Gramscian analyses, starting with Cox (1981)].

In reality, the explanation of national class struggles and international political relations by the place occupied by the national sphere in question within the global unity of capital accumulation, is not simply based on the recognition that capitalism is a global mode of production in content and national only in its form. It is based, fundamentally, on the recognition that capital is the dominant social relation and, as a consequence, all social relations are forms of its development. Definitively, it is based on the notion of capital being the concrete subject of the organisation of social life, since it is only from this point of view that political relations can be grasped as what they actually are, namely, concrete forms of the realisation of economic relations (Iñigo Carrera 2013: 95; Kicillof and Starosta 2007).

The Classic International Division of Labour as a Constitutive Part of the Current International Division of Labour

To account for the particular character of a national sphere of accumulation of capital we must, therefore, proceed from the immanent necessity of the global process of accumulation to differentiate itself into different national spheres. And this necessity can only spring out of the movement of the total social capital as the concrete subject of the organisation of social production. As is known, the *motor primus* of this movement is the production of relative surplus-value, which must therefore constitute the specific point of departure for the explanation of the role that each national sphere plays in the global unity of the accumulation of capital. More precisely, it concerns the development of the international division of labour that emerges from the materiality of the labour process belonging to the production of relative surplus-value. As we have seen, Marx did not manage to address the concrete forms in which the said unity of the global accumulation process is established through the world market. However, he did manage to show that this global unity and its corresponding national differentiation emerge out of the process of the production of relative surplus-value itself. More specifically, he located the basis of the polarisation of the world market in the most potent form of the development of this process, which is large-scale industry:

> [A]s soon as the factory system has attained a reasonable space to exist in, and reached a definite degree of maturity … as soon as the general conditions of production appropriate to large-scale industry have been established, this mode of production acquires an elasticity, a capacity for sudden extension by leaps and bounds, which comes up against no barriers but those presented by the availability of raw materials and the extent of sales outlets … A new and international division of labour springs up, one suited to the requirements of the main industrial countries, and it converts one part of the globe into a chiefly agricultural field of production for supplying the other part, which remains a pre-eminently industrial field. (Marx 1976: 579–80)[3]

That which Marx terms a 'new and international division of labour' appears to contrast with that which is currently also known as the 'new international division of labour' (NIDL) developed from the decades of the 1960s and 1970s (Fröbel et al. 1980), and whose basis is the 'transnational reorganisation of production … through the relocation … to new industrial sites where labour-power is cheap to buy, abundant and well-disciplined' (p. 15). However, as Grinberg and Starosta have noted, the course of historical development shows that the, so-called, NIDL did not result in the straightforward negation of the classical division of labour

(CIDL), but rather includes it as part of its substance (Grinberg and Starosta 2014: 241). In other words, one can currently find that within the NIDL there still are various countries that maintain their traditional role as producers of raw materials for the world market (Iñigo Carrera 2013: 65, 144 ff.). In this sense, Marx's cited text does not only retain validity but also, above all, confronts us directly with a question about the specificity of those national spheres of accumulation of capital that are based on the production of raw materials. What role do these national spheres play in the world market as the expression of the unity of the movement of global total social capital?

Ground-Rent and 'Resource Rich' Countries in the Global Unity of Capital Accumulation

The Loss of Surplus-Value by the Total Social Capital in the Form of Ground-Rent

The constitution of a national sphere based on the production of raw materials for the world market only makes sense to the extent that these raw materials are cheaper than if they were produced directly in the countries in which there is a demand. Furthermore, to the extent that these raw materials are commodities of agrarian or mining origin, this relative cheapness springs from the existence of relatively favourable natural conditions in the country that produces them. Ultimately, from the point of view of the global unity of the accumulation of capital, the constitution of a national sphere of this type only makes sense if the cheapening of the commodities that it supplies results in a lower value of labour-power exploited by the entire global total social capital, and in a growth in the corresponding rate of surplus-value.

However, the question is not as straightforward as it first appears. In contrast to common commodities, raw materials are normally bearers of a surplus-profit existing in the form of ground-rent, and the greater the relative favourability of the natural conditions in which they are produced, the greater the surplus-profit is. Consequently, the generation of national spheres specialised in the production of raw materials also implies the permanent transfer of a portion of global social surplus-value to landlords. As Grinberg and Starosta (2014: 241–2) argue, 'if, on the one hand, the total social capital enhanced its valorisation by reducing the value of labour-power, on the other this was partly offset by the drain of surplus-value, otherwise available for capital's appropriation, flowing into the pockets of domestic landowners in the form of ground rent'.

The question that arises at this point is, what is the origin of the surplus-value that constitutes ground-rent? From the point of view of the global accumulation of capital, if the surplus-value in question were the product of the labour of workers who produce raw materials, the generation of this type of national sphere would simply imply the failure to appropriate a part of the newly created surplus-value. However, if it did not concern the product of these workers' labour, it would imply the actual *loss* of a part of surplus-value that was appropriated before the existence of such national spheres. In this last case, the constitution of countries specialised in the production of raw materials would represent a greater contradiction for the global total social capital.

The question of the origin of surplus-value that constitutes ground-rent has been widely debated within Marxist scholarship. In essence, it is possible to distinguish two positions. On the one hand, some scholars consider that ground-rent—whether differential, absolute, or monopoly[4]—is surplus-value produced *within* the sector that produces raw materials. On the other hand, other authors argue that, with the exception of absolute rent, all forms of rent are constituted by surplus-value originating from *outside* the sector that produces raw materials. The first of these positions has been fundamentally developed by the Soviet tradition under the argument that the surplus-value that constitutes ground-rent emerges from the greater productivity of labour that produces the raw materials in question (Lapidus and Ostrovitianov 1929: 279; USSR Academy of Sciences 1957: 222–3; Vygodskiĭ 1974: 101). As I have argued elsewhere, the problem with this argument—and therefore with this position—is that it openly contradicts the most basic Marxian argument about value, according to which growth in the productivity of labour does not result in an increase in value, but in the growth of the quantity of use-values produced (Caligaris 2014a: 67). In contrast, the second of these positions, fundamentally developed in the 1970s by the Latin American Marxist tradition (Bartra 1979; Laclau 1969; Margulis 1979), argues that it is precisely because the labour that produces the raw materials in question is relatively more productive than the labour which determines their market price that the value that constitutes ground-rent has to be generated in another sector of social production. As was noted by the original contributors in this latter tradition, it concerns the same argument that Marx carefully developed in his examination of ground-rent and which led him to consider this portion of surplus-value to be ‘a false social value [which] results from the law of market value to which agricultural products are subjected’ (Marx 1981: 799).

Naturally, this essential determination of ground-rent does not change because a national border stands between the landlord and the industrial capitalist. Therefore, the ground-rent that is carried within raw materials exported from ‘resource rich countries’ is constituted by the surplus-value produced by foreign workers. As was argued early on by Laclau (1969: 294, author’s translation), this ground-rent ‘is surplus-value produced by the foreign worker which flows into the country’ supplying the raw materials. This means that the constitution of a national sphere specialised in the production of raw materials not only implies the cheapening of the labour-power consumed by industrial capital in general, but also that a mass of surplus-value which has not been generated therein flows permanently toward the national sphere in question. Such is the conclusion that follows from the worldwide development of the ‘law of value’, which is to say, from the movement of the global total social capital. Thus, this determination must constitute the point of departure for the entire explanation of the specificity of this type of national sphere of capital accumulation.

This conclusion openly contradicts all explanations of the specificity of the national economies in question based on analyses that posit the existence of a flow of surplus-value in an inverse direction, that is, on the existence of an outflow of surplus-value towards other countries, more specifically, toward those (mis-)termed ‘developed’, ‘core’, or ‘imperialist’ (for example, Emmanuel 1972; Marini 1991). Consequently, just as we discounted those explanations that were founded on the course of national class struggle or on international political relations, here we must also reject this other type of explanation that, even if not founded directly on the course of international political relations, is based on the existence of economic relations that contradict the essential determinations of ground-rent and, therefore, the law of value.

To conclude that a permanent mass of surplus-value produced by foreign workers flows toward the countries specialised in the production of raw materials would seem to contradict all the appearances presented by these national processes of capital accumulation. In effect, what would have to be expected in a country toward which there permanently flows an extraordinary mass of social wealth from abroad is a multiplied potential for the development of its national process of capital accumulation. Yet, what these countries normally present is a situation of recurrent crises, a permanently lower productivity of labour, low wages, an unusually large and historically growing surplus population, and so on.

The Potential for the Total Social Capital to Recover Part of the Surplus-Value Lost as Ground-Rent

Instead of abandoning the conclusion arrived at by the systematic development of the determinations of capital because it would appear to contradict immediate appearances, the path that the method of the critique of political economy opens up is precisely to continue developing such determinations. Therefore, what now has to be examined is how the release of surplus-value to the raw-material producing countries on the part of global total social capital transforms into its opposite, that is, into the *recovery* of this surplus-value.

First of all, the possibility of the recovery of lost surplus-value initially pocketed by landowners lies in the particular nature of the revenue that constitutes ground-rent. This form of revenue reproduces a social subject that plays no role in the immediate process of production, so that the appropriation of that part of the revenue by third parties does not affect the reproduction process in its unity. As Marx puts it:

> The capitalist is the direct exploiter of the workers, not only the direct appropriator but the direct creator of surplus-labour … he is himself a functionary of this production, its director. The landlord, on the other hand, has a claim—through landed property …—which enables him to pocket a part of this surplus-labour or surplus-value, to whose direction and creation he contributes nothing. Where there is a conflict, therefore, the capitalist regards him as a mere superfetation, a Sybarite excrescence, a parasite on capitalist production, the louse that sits upon him. (Marx 1989a: 539)

In effect, if the *normal profit* of capital is affected, the reproduction of capital is compromised and, with it, the process of production it puts in motion. Similarly, if the labourer's *normal wage* is affected it compromises her capacity to work, and therefore her capacity to produce surplus-value, obliging capital to interrupt the process of production. By contrast, nothing happens if the landlord's *normal ground-rent* is affected. It would seem that the total social capital has no other option but to get rid of the landowning class, taking directly into its hands the exercise of monopoly over the land, or rather, converting private property of the land into state property, so as to not have to cede to this parasitical class a part of the surplus-value generated by its own workers. This is precisely as Marx presents it:

> The abolition of landed property in the Ricardian sense, that is, its conversion into State property so that rent is paid to the State instead of to the landlord, is the ideal, the heart's desire, which springs from the deepest, inmost essence of capital. (Marx 1989b: 470)

However, the abolition of private property for a means of production as significant as the land cannot be realised without calling into question the private property for the rest of the means of production and private property in general. Thus considered, it would appear that the total social capital has no option but to live with the landowning class and, therefore, to cede to it all surplus-value corresponding to the form of ground-rent. Marx also underlines this point:

> The radical bourgeois … therefore goes forward theoretically to a refutation of the private ownership of the land, which, in the form of state property, he would like to turn into the *common property* of the bourgeois class, of capital. But in practice he lacks the courage, since an attack on one form of property—a form of the private ownership of a condition of labour—might cast considerable doubts on the other form. (Marx 1989a: 278)

The recovery by the total social capital of the surplus-value produced by its workers but which ends up in the hands of landlords in the form of ground-rent contains, then, a contradiction. On the one hand, a recovery could be possible insofar as landlords are mere social parasites and, therefore, useless for the entire process of the accumulation of capital; on the other hand, doing away with landlords would imply jeopardising private property of the land and, along with it, the very process of capital accumulation. Marx presents the development of his contradiction in the following way:

> Capital cannot abolish landed property. But by converting it into rent [which is paid to the State] the capitalists as a *class* appropriate it and use it to defray their State expenses, thus appropriating in a roundabout way what cannot be retained directly. (Marx 1989b: 470)

In summary, insofar as ground-rent is a mass of value that the landlord appropriates only by virtue of the economic relation she personifies, the total social capital can appropriate from her through the power of the state. However, precisely because ground-rent is revenue accruing to the private property of land, this appropriation is quantitatively limited by the very questioning of private property that it entails.

Now, the total social capital that Marx develops is, in reality, the global total social capital. For its part, the political representation of the global total social capital by the state is mediated by the national form taken by the accumulation process, that is, by the existence of national total social capital as an aliquot part of the global total social capital. Therefore, the appropriation of ground-rent by the total social capital through the state must take shape, first of all, in the appropriation of ground-rent by the national total social capital of 'resource rich' countries through their own national states.

THE CONCRETE FORM THROUGH WHICH GROUND-RENT ACCRUES TO THE NATIONAL LANDLORD CLASS AND THE LIMITS TO A PROCESS OF CAPITAL ACCUMULATION BASED ON THE PRODUCTION OF RAW MATERIALS: THE CASE OF ARGENTINA

Since it is mediated by the national form taken by capital accumulation, the question of the global total social capital's recovery of ground-rent flowing into 'resource rich' countries can only be developed by examining a particular national case. Iñigo Carrera (1999, 2006, 2007) has taken on this task in the case of Argentina.[5] In what follows, I offer a sketch of the Argentinean case to illustrate the concrete forms that the appropriation of ground rent flowing into 'resource rich' countries can take and, in turn, by the specific form such countries take by virtue of such forms of appropriation. Unless indicated, this brief account is based on the work of Iñigo Carrera.

The Forms Taken by the Recovery of Ground-Rent

A first form of recovering ground-rent is through direct taxation, that is, straight out of the landowner's pocket. This form was attempted in Argentina in 1973 under the tax on potential ground-rent (*Impuesto a la*

Renta Normal Potencial de la Tierra), but it has never been applied effectively (Nuñez Miñana 1985).[6] The reason for its ineffective application is not to be found in the abstract political power of the landowning class, but in the 'confiscatory' character, or the violation of the principle of fiscal equity, that this tax would entail given the mass of value at stake (Iñigo Carrera 2007: 120). In particular, given the natural differences between lands, this confiscatory character would represent a violent fiscal inequity that would divide the landowning class. But also, and fundamentally, it would affront the entirety of capital. For this reason, as Marx would say, this tax could not but remain merely the heart's desire of the Argentine and foreign capitalist class.

A second form of taking ground-rent from the landowner is to impose a general tax, not on the value captured by each particular landowner, but on the commodities that are bearers of ground-rent. The fact that this tax is applied, in the last instance, to the portion of ground-rent materialised in the commodity and not to constant capital, variable capital, or the profit materialised in the commodity itself, is explained with reference to the nature of the revenue that ground-rent constitutes. If the tax is imposed on capital, whatever its part, it would directly affect the material production of the commodities in question and, in the end, the very collection of the tax imposed. On the other hand, if ground-rent is affected, material production continues as normal. This tax has appeared time and again in Argentinean history in the case of agrarian commodities destined for export. However, the amount of this tax has always been limited with respect to the amount of ground-rent in circulation (Iñigo Carrera 2007: 88–90). In effect, beyond a certain magnitude, it also appears to have a confiscatory character and/or to be in violation of fiscal equity. In spite of this, and in contrast with the tax on potential ground-rent, this type of tax constitutes a real form of the appropriation of ground-rent.

The effect of taxes on exports does not end, however, with the commodities on which they are directly applied. Through the mediation of competition, the taxes on commodities destined for the world market reduce the price for the same type of commodities destined for the domestic market. Whomever purchases these cheapened commodities domestically, therefore, are themselves appropriating a mass of ground-rent in the same way as the state when it collects the tax on the raw materials being exported (Iñigo Carrera 2007: 20). Nevertheless, neither the working class that consumes these commodities nor the state are the end beneficiaries of this appropriation. Instead, and insofar as those commodities are usually 'wage goods', the end beneficiaries are generally individual capitals that end up purchasing labour-power more cheaply without affecting the latter's reproduction.

A third form of appropriating ground-rent from the landlord is to directly regulate the internal prices of raw materials. The same mechanism operates here as the application of a tax on exports. Consumers (that is, wage workers) pay a market price for the commodities in question that is less than the normal price, thus cheapening labour-power and thereby transferring a part of the ground-rent contained within them to its buyers (that is, individual capitals). The forms of regulation the state can bring to bear on internal prices are varied. In Argentina, the fixing of maximum prices for certain commodities and the existence of export quotas has predominated. However, the most potent form of this appropriation has been during brief periods in which the state directly purchased ground-rent bearing commodities at lower market prices than normal prices, in order to sell them later at a higher level. In this case the state enacts a direct appropriation of ground-rent, that is, without the mediation of individual or productive consumption that occurs under the other types of regulation of internal prices (Iñigo Carrera 2007: 88–90). Evidently, this form of appropriation of ground-rent entails the same limits carried by export taxes. As soon as a certain threshold of the rate of taxation is reached, its confiscatory character or the fiscal inequity involved becomes apparent. For this reason, the appropriation of ground-rent through the direct regulation of the prices of raw materials has been a relatively small proportion of the total mass of ground-rent available for capture. Moreover, its implementation has alternated with the application of export taxes.

Until now it would appear that, given the contradiction between the capturing of ground-rent from the landowner and the right to private property, the global total social capital could only recover a very limited portion of the ground-rent in question. However, there exists a mechanism of recuperation that, because of its veiled and also indirect character, manages to escape this contradiction and therefore allows for the recovery of ground-rent some way beyond the forms recently analysed. It concerns the overvaluation of the national currency in relation to the currency that functions as world money—historically, the US dollar (Iñigo Carrera 2007: 19). Because of its potency, this mechanism has been a constant in the history of the Argentine process of capital accumulation and is what explains its specific character. Before analysing it, and in order to give a clearer idea of its importance, note in Fig. 3.1 the magnitude and recurrence with which it appears in the course of the historical development of the Argentine national process of capital accumulation.

The overvaluation of the national currency means that whomever exchanges foreign currency for national money receives a lesser quantity of social wealth than they would receive if this type of exchange were at parity. To the extent that foreign currency enters the country by means of exports, the overvaluation of the local currency means that capitals that export must possess a surplus-profit that can be lost in the process of exchange without affecting their normal reproduction. In countries specialised in the production of raw materials this extraordinary profit is nothing but the ground-rent carried in agrarian and mineral commodities that are being exported.

The destination of the ground-rent retained in the foreign exchange mediation is varied, but two immediately appear. In the first place, the said ground-rent can end up in the pockets of importers that, due to the same currency overvaluation, need to pay out a lesser quantity of social wealth in order to acquire the foreign money with which they buy imported commodities. In the second place, it can end up in the hands of the state through extraordinary taxes on imports that compensate for the effect of the overvaluation of the national currency by raising the prices of imports to their normal price.

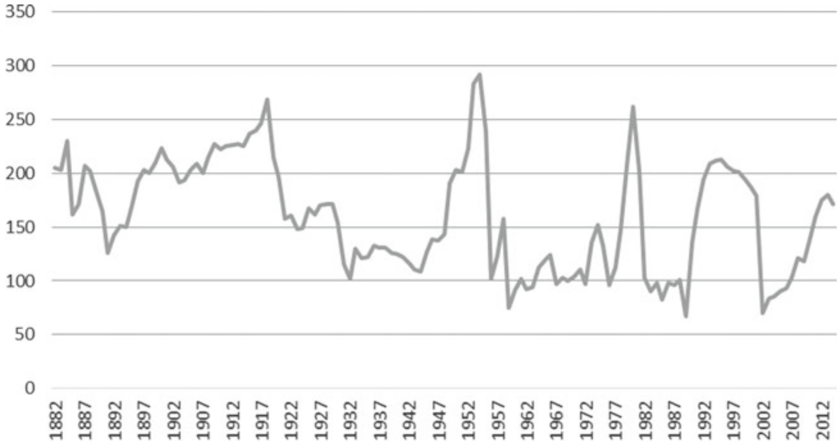

Fig. 3.1 Overvaluation of national currency, Argentina (1882–2014)

Source: Iñigo Carrera (2007), updated to 2014 on the same methodological basis

As in the case of export taxes, the effect on the prices of raw materials that are exported provoked by the overvaluation of the currency is automatically transferred to the same commodities that are consumed internally, so that the overvaluation also indirectly opens another route for the transfer of ground-rent. The appropriators in the first instance are the consumers of these commodities, although they are evidently not the final beneficiaries.

The Appropriation of Ground-Rent by the Total Social Capital and the Limits to a National Process of Accumulation Specialised in the Production of Raw Materials

Until now we have considered the historically most relevant mechanisms that, mediated by the political action of the national state as direct general representative of the global total social capital, have been developed so as to recover ground-rent from Argentine landlords. The question that remains is what the global total social capital has done to finally appropriate it for itself? Before answering this, or rather, as the first step in a response, we consider how the global total social capital presently acts in the Argentine national process—that is, how the capital that accumulates in this national space of valorisation acts, as a whole, and as an aliquot part of the global total social capital.

At first glance, it would seem that the global total social capital behaves in Argentina as it does in any of its other national forms. First of all, it is clear that a good part of the capital in question is of foreign origin. However, in contradistinction to the rest of the world, what characterises the foreign capital that accumulates in this country is that it produces on a scale restricted to the domestic market (see also Chap. 8). Indeed, if we take into account the degree and the historical recurrence of the overvaluation of the national currency, this characteristic should come as no surprise: insofar as the commodities produced by those capitals do not yield a permanent source of extraordinary profit, the existence of an overvalued currency prevents them from being exported without affecting the normal reproduction of capital. What does spring to attention, on the other hand, is the question of how it is possible to reproduce those normal capitals in as small an internal market as that of Argentina. Iñigo Carrera makes this clear in the case of the automotive industry:

> How do they fit into a market of only 36 million inhabitants, almost half of whom live below the poverty line today and whose average wage is just one tenth of the American wage? For instance, six of the world's main car manufacturers still have production plants in Argentina. Each export to the Mercosur zone is met by an import, thus balancing out any expansion of the scale of production, beyond that of the internal market. Conversely, in Italy, with a population that is two thirds larger and an average wage close to the American one, there is only one car manufacturer which is, furthermore, unable to sustain independent capital ownership. (Iñigo Carrera 2006: 193)

In effect, to produce exclusively for an internal market like that of Argentina means to produce on a small scale and, as a consequence, to produce with higher costs. In this context, to yield a normal rate of profit it is necessary to depend upon an alternative source of surplus-value that compensates for those higher production costs. Of course, one such source can be the circumstantial purchasing of labour-power below its value. Another can be the surplus-value released by small capitals that are linked together with the 'foreign' capitals in circulation (that is, in 'global value chains'—see Starosta 2010). But neither of those two phenomena can be the basis of the normal accumulation of capital in Argentina. If that were the case, instead of limiting themselves to the internal market, industrial capitals would basically produce for the world market (Iñigo Carrera 2006: 194). In fact, the essential source of surplus-value that compensates for the higher costs incurred by normal capitals is nothing other than the ground-rent that they capture from landlords through the mechanisms analysed above.

The normal capitals that accumulate in Argentina appropriate this ground-rent in various ways. The most significant are the following. To the extent that this rent falls directly into the hands of the national state—via taxes on exports, direct control of foreign trade, or taxes on imports that compensate for the overvaluation of local currency—it flows toward the capitals in question through subsidies, tax exemptions, the purchasing of their commodities, and so on. To the extent that ground-rent falls into the hands of the working class through the purchasing of agrarian commodities cheapened by the effect of taxes on exports or the overvaluation of the local currency, it is automatically transferred to capital in the form of a cheapening of the value of labour-power. To the extent that ground-rent is retained in the foreign exchange mediation by the overvaluation of the local currency, it is appropriated by capital through the purchase of cheapened imported means of production or the multiplication of the remission of its profits abroad.

In its unity, however, this appropriation of ground-rent by the global total social capital, in particular that which develops through the accumulation of normal capital, contains an insuperable contradiction. On the one hand, the overvaluation of the local currency, given its indirect and veiled character, is the only form in which a sufficiently compensatory quantity of ground-rent can be appropriated. On the other hand, this same form restricts the accumulation of normal capital to the internal market and therefore, given the size of this market, means the restriction of its scale of production. The result is a process in which global total social capital succeeds in appropriating ground-rent but, at the same time, does so at the expense of limiting the national process of accumulation in question. Thus, normal capitals that accumulate in this kind of country are limited by the quantity of available ground-rent that compensates for the difference between their scales of production and those that prevail on the world market, which are constantly increasing in scale. Meanwhile, the working population continues to grow and to swell the ranks of the superfluous population.

In summary, looking at the case of Argentina one can conclude, first, that the potentiality for the global total social capital to recuperate the surplus-value that flows toward resource rich countries in the form of ground-rent takes a whole series of possible concrete forms of realisation. And, second, that the nature of these forms of recuperation necessarily generates a limit to the expansion of the process of capital accumulation in the country in question.

Conclusion

This chapter has sought to offer a general explanation of the distinctive characteristics presented by countries specialised in the production of raw materials that does not contradict the fundamentals of the Marxian critique of political economy. With this methodological approach, the point of departure has been to recuperate the Marxian perspective according to which the process of capital accumulation that regulates our lives is essentially global and that, therefore, all national specificity has to be explained by the role that the country plays in correspondence with the global unity of the accumulation of capital. This viewpoint plainly contradicts any explanation based on the struggle of local classes, in international political relations, or in the conjunction of both. More specifically, these relations are nothing more than the mediating forms through which the movement of the global total social capital realises itself as the concrete subject of the organisation of social life.

By recognising that countries specialised in the production of raw materials are *organs* of the global process of capital accumulation, we have acknowledged that international economic relations are essential in explaining the specificity of raw-material producing countries. However, in contraposition to the theories that encounter in these economic relations some type of unequal exchange against 'resource rich' or 'peripheral' countries, we have seen that what concretely occurs in international trade is entirely to the contrary, that is, it is the 'resource rich' countries that receive a flow of the global social surplus-value not originally produced by them, in the form of ground-rent. The examination of the particular nature of the revenue constituted by ground-rent has confronted us with the potentiality for the global total social capital to recuperate part of the surplus-value lost in the purchasing of raw materials through the mediation of policies applied by the national states of the 'resource rich' countries. The Argentine case has shown that this potentiality is realised in a whole series of concrete forms. More importantly still, this case also demonstrates that, given their nature, these forms of recuperation of ground-rent generate the existence of a specific limit to the expansion of the process of capital accumulation in this type of countries, that which is consistent with the conditions of impoverishment normally evident therein. Of course, the conclusions drawn from the analysis of the Argentine case cannot be generalised in a mechanical and automatic manner to any country specialised in the production of raw materials. On the contrary, every case has to be examined in its specificity. In this sense, the objective of this chapter has been merely to set out a basis for carrying out this type of research.

NOTES

1. The term 'total social capital' is the usual English translation of what Marx variously terms '*gesamte gesellschaftliche Kapital*', '*gesellschaftlichen Gesamtkapitals*', or simply '*gesellschaftliche Kapitals*' in the original German.
2. The consideration of a national space of valorisation as an organic element of the worldwide accumulation process requires that we go beyond Marx and explicitly distinguish between the total social capital as the unity of all individual capitals and, in a more limited sense, as the unity of all individual

capitals that function within a national territory. In line with the Marxian terminology, I shall refer to the former as the *global total social capital* and to the latter as the *national total social capital*. Note, however, that national in the latter term does not refer to the nationality of the owners of capital but to the fact that this part of capital is valorised within the respective national territory.

3. In line with his systematic presentation of the determinations of capital as the dominant social relation, Marx was conscious of the fact that the explanation of the global unity of the accumulation of capital would not correspond to the planned book on 'the process of the production of capital' but, as noted earlier, to the book on the 'world market'. For this reason, Marx precedes this development by clarifying that he will refer 'to relations of a purely practical nature, the existence of which has not yet been revealed by our theoretical presentation' (Marx 1976: 578). This affirmation by Marx contrasts strongly with the interpretation proposed by Pradella (2013), who sees *Capital* as a systematic development of international relations.
4. Traditional readings distinguish three types of ground-rent: differential rent of types I and II that arise out of differences in fertility and/or the location of lands; and the absolute rent that emerges from the lower organic composition of capital invested in the worst land (Kautsky 1988). More recent readings have further distinguished the simple monopoly rent that emerges from the market power of the landlord class (Harvey 1973). Of course, this typology, as well as the definition of each type of ground-rent, is not free from controversy. For a synthesis of main debates, see Caligaris (2014a, b).
5. For an analysis of Brazil on this basis, see Grinberg (2008, 2011, 2013).
6. The first official draft of a tax on potential ground-rent was developed in the early 1960s. After several public discussions, in 1973 the tax obtained the status of national law (Law No. 20,538/73). However, this tax was never fully applied because the surveying and cadastral valuation of lands the law demanded were not carried out. For more information see Nuñez Miñana (1985).

CHAPTER 4

Revisiting the New International Division of Labour Thesis

Guido Starosta

Despite being highly influential during the first half of the 1980s, the new international division of labour (NIDL) thesis advanced by Fröbel et al. (1980) seemed to fall out of favour in the 1990s. Prompted principally by some empirical developments which seemed to contradict the major claims of the NIDL thesis (especially the industrial upgrading of the first generation of 'Asian Tigers', which would eventually include relatively complex, 'capital-intensive' sectors rather than simply unskilled-labour-intensive ones, as predicted by Fröbel, Heinrichs and Kreye), many scholars then started to voice strong reservations about the NIDL approach. While many of these objections uncovered real weaknesses in the NIDL thesis, I argue that the critics' alternative explanations were not free from shortcomings themselves, and that debates on late-industrialisation eventually threw the baby out with the bath water. I show that many of those critiques were misguided and that there still is much of value to be recovered from the original insights contained in Fröbel, Heinrichs and Kreye's contribution for a critical approach to the contemporary dynamics of the international division of labour.

The goal of this chapter is therefore to offer a critical reformulation of the NIDL thesis which preserves its rational kernel yet abandons its most contentious points. I argue that the former resides in its global perspective on capital accumulation and in the centrality attributed to recent material transformations in the capitalist labour process as key to the explanation of the developmental potentialities of late-industrialisation. The latter relate to weaknesses in Fröbel, Heinrichs and Kreye's conceptualisation of the changing material configuration of the production process in capitalism, and to their inability to offer a firmly grounded explanation for the resilience of the classical international division of labour (CIDL) in certain regions of the world (for instance, Latin America—see Chaps. 2, 3 and 5). On this basis, this chapter further submits that a revised NIDL thesis can shed new light on the specificities of 'export-led industrialisation' in the 'Third World', especially on East Asian developmental processes.

The New International Division of Labour Debate

Before reviewing the debates that emerged around Fröbel, Heinrichs and Kreye's work in the 1970s, it is worth briefly summarising the general thrust of the argument normally attributed to it. The popularised version of the NIDL thesis on the process of global restructuring argues that, faced with declining profitability in advanced capitalist countries (mainly due to rising wages), transnational corporations (TNCs) started to relocate labour-intensive manufacturing to the, then so-called, Third World, thus acting as a major factor in the industrial decline that seemed to prevail in the former countries in the late 1970s and early 1980s. Third World countries, for their part, provided TNCs with a huge potential reserve of cheap and disciplined labour-power. Combined with technological advances in the means of communication and transport, the increasing fragmentation of production processes and the consequent simplification of semi-skilled and unskilled tasks together created a tendency for the establishment of export-oriented world market factories in the Third World. Accordingly, the 'classical' international division of labour (CIDL)—revolving around the polarisation of the world economy into an industrialised 'core' and a dependent 'periphery' confined to the role of supplier of raw materials and staple foods—had been superseded by the NIDL, with an industrialised but still dependent Third World, and a 'First World' oriented to a service-based economy, which could not absorb the resulting unemployed population.

A first point made by several critics of this NIDL thesis has been that TNC competitive strategies have not been reduced to the search for world-market production sites based on cheap and compliant labour-power. This excessive emphasis on cost minimisation and the supply of ‘factors of production’ ignores that corporations also consider revenue maximisation and output markets when making decisions on the geographical location of production (Schoenberger 1989: 92). In this sense, the NIDL thesis allegedly overlooked that, in certain regions of the ‘developing’ world, foreign direct investment (FDI) in the last thirty to forty years has been driven to take advantage of profitable domestic markets (for instance, in sectors like the automotive and chemical industries) (Fagan and Webber 1999: 38; Jenkins 1984). Moreover, TNCs have continued to invest in new raw material ventures and agribusiness.

Despite much emphasis by critics on this point, Fröbel, Heinrichs and Kreye were aware of this. Indeed, they acknowledged that the emergence of the NIDL ‘does not mean that capital no longer exploits the possible benefits of production in countries whose local market is protected’ (Fröbel 1982: 511). It was also clear to them that the establishment of world market factories did not imply that investment in the production of agricultural and mineral raw materials (including its processed derivatives, as in agribusiness), which take advantage of privileged non-reproducible natural conditions like exceptional fertility of the soil, would necessarily come to a halt (Fröbel 1982: 512). Presumably, their argumentative strategy was to highlight the *novel* developmental *tendencies* of global accumulation, with the awareness that ‘the concretization, modification, or transcendence of this trends and tendencies through “local” particular circumstances will require further research’ (Fröbel 1982: 508).

And yet, it is fair to say that Fröbel, Heinrichs and Kreye *did* underestimate the resilience of the CIDL and tended to overgeneralise the potentialities of those newer developmental tendencies in the geography of global capitalism. For instance, their empirical study included evidence from Brazil as an example of the incipient establishment of world-market factories (Fröbel et al. 1980: 304ff.). However, Brazil is one of the most paradigmatic cases (alongside Argentina) of precisely the opposite tendency: *the persistence of the CIDL* and its enduring (albeit decreasing) potentiality to sustain industrialisation processes oriented towards protected domestic (or regional, that is Mercosur) markets in ‘peripheral’ countries (Iñigo Carrera 2007; Grinberg 2008). The truth of the matter is that the emergence and development of the NIDL did not entail overcoming the

CIDL. Both modalities coexist in the contemporary configuration of the world market, which leads to a more complex form through which the formal/material unity of the global accumulation process is achieved. This is a crucial insight, already advanced by Iñigo Carrera and Caligaris in Chaps. 2 and 3.[1]

Critics have further argued that the NIDL thesis also erred in its prognosis of the fate of the accumulation process in the 'First World'. In effect, the strong claims for the tendency to de-industrialisation of the former heartlands of capitalism were too heavily reliant on very specific assumptions about the evolution of the production process being one of a fragmentation of tasks and the deskilling and standardisation of products (Schoenberger 1988; Sayer 1986). However, restructuring in advanced national spaces of accumulation through the further automation of the labour process was an alternative strategy that TNCs have actually pursued together with the relocation of production (Schoenberger 1988, 1989). In other words, manufacturing could be 'relocated back north' (Cho 1985; Nanda 2000; Oberhauser 1990).

Inasmuch as Fröbel and his colleagues did one-sidedly emphasise the transformative dynamics in the 'global south' without shedding much light on the kind of mutations undergone by advanced capitalist countries, those critiques rightly uncovered one of the central limitations of the original formulation of the NIDL thesis. However, the particular arguments put forward did not rest on very solid foundations either. As the empirical discussion of the evolution of the Brazilian and South Korean steel industries by Grinberg in Chap. 9 shows, for example, the greater 'capital-intensity' of more highly automated labour processes has not precluded their relocation to 'peripheral countries'. In this sense, the general validity of the NIDL thesis does not rest on any particular assumption about the 'capital-intensity' of the production process.[2] The key issue concerns the relative cheapness and discipline of certain kinds of labour-power, whether in manual assembly tasks *or* as machine-operators in a more automated labour process.[3] What matters for the spatial implications of transformations in the capitalist labour process, is whether the production of workers with the varied qualities of labour-power required by the different tasks associated with an increasingly automated labour process, takes a shorter time, and therefore costs less, than before the introduction of technological change. Note that this point also applies to intellectual labour. Insofar as the latter also becomes *relatively* simplified, the exploitation of the consequently less complex forms of intellectual labour-power can also be relocated to countries where capital finds those kinds of workers more cheaply and with a more compliant subjectivity, as the current literature on offshoring of innovation and creative labour illustrates (Ernst 2005; Huws 2006, 2014). Thus, we shall see that industrial upgrading and the concomitant increase in real wages in countries like South Korea, and hence the subsequent development of hierarchically-structured *regionalised* production networks (Hart Landsberg and Burkett 1998; Bernard and Ravenhill 1995), is perfectly consistent with the NIDL thesis, rather than its negation, as some critics tended to assume (for example, Fagan and Webber 1999; Henderson 1989).[4]

On the other hand, the renewed wave of international migration by workers and the dismantling of state policies supporting the relatively undifferentiated reproduction of the different segments of the working class (that is, the so-called welfare state) have meant that capital did not necessarily need to relocate to benefit from the advantages of the NIDL. It could also *recreate* the general content of the NIDL within its national territory by accentuating the differentiation of the conditions of exploitation and reproduction of labour-power of heterogeneous complexities through the superimposition of the formal mediation of citizenship (and/or through the reassertion of the formal mediations of race, ethnicity, and gender) (see also Chap. 7).[5]

Finally, an intimately related objection put forward by critics stated that the NIDL thesis overstressed the role of TNCs in shaping the contours of the world market and failed to acknowledge the 'agency' of indigenous firms from the 'periphery' (Fagan and Webber 1999: 39). I argue that it is grounded in both a misreading of Fröbel, Heinrichs and Kreye's argument and, more importantly, in a misunderstanding of the actual determinant of the emergence of the NIDL, namely, the changing material conditions in *the process of valorisation of industrial capital on a global scale*. Irrespective of the 'nationality' of industrial capitals, this process, directly or indirectly, minimises the total cost of reproduction of the *global* working class and thus increases the rate of valorisation of global capital as a whole. The relevant question here is the spatial relocation of capital's valorisation process as such, not that of individual capitalist firms.[6] The emergence, consolidation, and even market leadership of 'national champions' from the 'periphery' (for example, the growth and industrial upgrading of Korean *chaebols*), has been as much an expression of the NIDL as world market-oriented FDI by TNCs. As Grinberg's discussion of the Korean steelmaker POSCO in Chap. 9 demonstrates, the objective basis of its global competitiveness and consequent success has been the same that attracted international investment by TNCs elsewhere in East Asia (or in other sectors of Korea), namely, the harsh exploitation of the domestic pool of relatively cheaper and more compliant wage-workers, which was in turn made possible by the prior material transformation of the steelmaking labour process that downgraded the requisite productive attributes of the respective collective labourer.

In sum, the global process of industrial restructuring has involved both automation-based technological change *and* spatial relocation. But these have not been mutually exclusive or contingently related competitive strategies pursued by TNCs, but different *forms* taken by the same intrinsically global *content*; the novel quality of the production of relative surplus-value on a world scale by *capital as a whole*. The next section further elaborates on this fundamental point.

A Marxian Re-examination of the New International Division of Labour Thesis

One of the strengths of Fröbel, Heinrichs and Kreye's contribution, which sets it apart from most of their critics in the view of the contributors to this book, derives from an analysis that was firmly rooted in the essentially global nature of the capitalist valorisation process. In other words, the world market was not regarded simply as the sum total of national economies interconnected through external trade and capital flows. Instead, Fröbel, Heinrichs and Kreye conceived of national economies as 'organic elements of one all-embracing system, namely a world economy which is in fact a single world-wide capitalist system' (1980: 8). Furthermore, and following from the previous point, their approach did not consider nation-state policies as 'autonomous' forces that determine the specific structure of national markets and processes of capital accumulation. These were seen as *political mediations* of the integration, through the international division of labour, of the *intrinsically global economic content* of the process of capitalist development, whose 'determining force, the prime mover … is therefore the valorisation and accumulation process of capital' (1980: 25). Accordingly, they rightly saw the emergence of the NIDL not as being *driven* by the deliberate strategies of states or of TNCs but, rather, as the 'unconscious' result of a qualitative change in the conditions of the autonomously regulated global process of capital accumulation.

The following passage from their book is eloquent and unequivocal in this respect, so it is worth quoting at length:

> We therefore interpret the currently observable relocation of production in industry (both within the traditional 'centre' and towards the 'periphery'), and in addition the increasing world-wide subdivision of the production process into separate partial processes as being the result of a qualitative change in the conditions for the valorisation and accumulation of capital, which is forcing the development of a new international division of labour. This new international division of labour is an 'institutional' innovation of capital itself, necessitated by changed conditions, and not the result of changed development strategies by individual countries or options freely decided upon by so-called multinational companies. It is a consequence and not a cause of these new conditions that various countries and companies have to tailor their policies and profit-maximising strategies to these new conditions (that is, to the requirements of the world market for industrial sites) (1980: 46).

Unfortunately, the general determinations behind this fundamental insight were insufficiently elaborated by Fröbel, Heinrichs and Kreye, thus opening the space for some of the misguided criticisms reviewed above. Moreover, the theoretical arguments that they did flesh out were based on a rather eclectic synthesis of Marxist and world-systems/dependency theory terminology that, in my view, did not contribute to the rigour and clarity of their discussion.[7] Specifically, what was missing from their otherwise insightful work is therefore a more rigorous inquiry into the general nature of capital as a *fetishised social relation*.

One of the most potent scientific discoveries of Marx's critique of political economy was that capital is neither a thing (for example, the instruments of production), nor a productive unit or legal entity (that is, a firm), nor a social grouping sharing common characteristics and interests (business elites). In its general determination as *self-valorising value*, capital is actually a *materialised* social relation between commodity-owners differentiated into social classes, which becomes inverted into the very (alienated) subject of the process of social reproduction in its unity (Marx 1976: 763). Thus, capital is essentially the formally boundless movement of self-expansion of the objectified general social relation between private and independent individuals which, in its own process, produces and reproduces the latter as members of antagonistic social classes (Marx 1976: 251–7, 1978: 185).[8]

Moreover, as an expression of this inherently self-expansive nature, this fetishised social relation is global in content or substance and national only in form (Iñigo Carrera 2013: 144–5; Marx 1993: 227–8). This means that it is 'the self-valorisation of value' on a global scale, or accumulation on the level of the 'total social capital', that constitutes the immanent end in the world market (Smith 2006: 193). The territorial or spatial dimension of the accumulation process—and the changing forms of the worldwide division of labour—therefore cannot be seen as *determined* by the locational strategies of TNCs faced with given qualitative national and regional differences, in turn seen as established by allegedly autonomous state policies. Instead, it needs to be grasped as an expression of the underlying formal and material unity of the essentially global contradictory dynamics accumulation of the total social capital, which are *economically mediated* by relations of competition among individual capitals like TNCs (again, as opposed to *determined*), on the one hand, and *politically mediated* by the policies of the nation-state on the other (Clarke 2001). As Burnham (1994) states against traditional Marxist theories of the global political economy, the immanent *content* of these global dynamics is not one of imperialism or dependency (that is, a direct political relation between states, another mediating *form*), but those of the production of (relative) surplus-value on a world scale (see also Howe 1981). In other words, the foundation of the uneven spatial differentiation of global capitalism must be searched for in the changing forms of the exploitation of the global working class by the total social capital through the transformation of the material forms of the capitalist production process. The latter is, in sum, the general economic content that is realised in the political form of state policies (domestic and foreign) and class conflict, albeit 'behind the backs' of the antagonistic actions of the personifications involved (social classes and their diverse political organisations, 'political elites' and/or 'state managers'). These contradictory and crisis-ridden dynamics, which fundamentally entail a permanent revolution in the modes of exertion of the labour-power of individual workers and of their articulation as a directly collective productive body (Marx 1976: 617), lie at the heart of the contemporary forms of the international division of labour.

Here we find one of the central weaknesses in the original formulation of the NIDL thesis, for, as Grinberg (2011) perceptively notes, the foundation of the emergence of the NIDL does not reside in the intensification of the *manufacturing division of labour*, that is, in the 'deskilling' resulting from the 'subdivision of the production process into elements' (Fröbel et al. 1980: 37ff). Instead, as Iñigo Carrera (2013) shows in his alternative account of the NIDL, it developed as an expression of the impact that the progress of the *automation* of capitalist *large-scale industry* had on the individual and collective productive subjectivity of the working class.[9] More specifically, the constitution of the NIDL has been the result of the transformation of the modes of existence of the global collective labourer brought about by a leap forward in the process of computerisation and robotisation of the production processes of large-scale industry, especially since the microelectronics revolution. Let us examine these productive changes more closely.

As is a general tendency in large-scale industry, these transformations have revolved around a threefold qualitative differentiation in the evolution of the labour-power of the members of the collective worker. In the first place, they have involved the *expansion* of the productive attributes of those wage-labourers performing the more complex parts of the labour process, that is, all those forms of (mainly) intellectual and scientific labour which are required for a leap forward in the automation of the system of machinery, both through the computerisation of their calibration and control, and through the robotisation of assembly and machine feeding. This has not only included the expansion of the productive subjectivity of those wage-labourers responsible for the development of the power to regulate in an objective and increasingly universal fashion the movement of natural forces, that is science. It has also included the multiplication of the human capacity to incorporate science in the immediate process of production, both through its technological applications in the systems of machinery and through the conscious practical organisation of the unity of productive cooperation based *machino*facturing. As Marx already anticipated in *Capital*, this development of the intellectual powers of humanity has taken on a separate existence vis-à-vis *direct* labourers in the immediate process of production, expressed in this context both in the growing importance of R&D labour and in the expansion of white-collar work involved in the programming of machine-tools and the planning of large-scale industrial production (as the latter activities became increasingly removed from the shop-floor). Yet, sooner or later many of these intellectual dimensions of living labour have also been subjected to the development of automation (or codification of knowledge) and therefore relatively simplified (e.g. the case of computer-aided design).

In the second place, these novel technological forms entailed a further step in the expulsion of the intervention of the human hand and of the experienced-based practical knowledge of workers in the labour-process vis-à-vis the forms that dominated the previous historical cycle of accumulation. Indeed, these productive changes have accelerated the codification of *tacit* knowledge, previously embodied in the manual industrial worker and largely acquired through lengthy on-the-job, learning-by-doing processes. Once codified, this knowledge has been objectified as an attribute of the system of machinery (Balconi 2002; Huws 2006, 2014). In this sense, the tendency has been one of deskilling or degradation of direct production work, although not as a result of the furthering of the manufacturing division of labour, as Fröbel et al. would have it, but through the objectification of formerly manual tasks as automated functions of machines. Now, this implementation of computer-based automation has also involved, alongside the redundancy of *old* skills, the creation of *new* ones, not only in the cases of laboratory and office work mentioned above, but also on the shop-floor. Thus, the effect of increasing automation on the productive subjectivity of direct production workers has not just been one of deskilling, but has been mixed, also entailing a certain up-skilling. However, the crucial point here, often missed in the debates on the impact of, so-called, flexible technologies, is that these newly emerging productive attributes have been of a *different kind* from those that had been lost. While the overall result has been a tendency for the degradation of those *particularistic* productive attributes (both manual and intellectual) which can only be slowly developed through the practical experience of machining in the direct process of production, many of the newly created skills—from familiarity with computers to flexibility or individual initiative in problem-solving or decision-making—have tended to revolve around the *universalistic* dimension of the productive quality of labour-power (so-called soft or generic skills; see Ramioul 2006), whose development is achieved in the general process of education and socialisation that precedes its actual application in the production process.[10] Note, however, that the fact that many of these latter skills can be said to be head based, that is involving controlling, planning, and consciously remembering (cf. Hirschhorn and Mokray 1992), does not mean that they are necessarily highly *complex* activities in the sense of requiring a longer process of training of the requisite kind of productive subjectivity (Coriat 1992: 183–4).[11]

In the third place, while the new technologies have not resulted in the total elimination of manual labour from automated processes of production (Alcorta 1999: 164), they have recreated the conditions for the extended reproduction of what Marx called the *modern* manufacturing division of labour, that is those non-mechanised tasks and labour processes acting as an '*external department*' of large-scale industry proper as the dominant form (Marx 1976: 588ff). Thus, the assembly process in many industries has remained heavily dependent on the manual skills of labourers. Other industries have been particularly resilient to mechanisation, given the current technical impossibility of replacing the subtlety of the movement of the human hand when dealing with certain materials (e.g. the clothing industry) (Walker 1989). Furthermore, the new technological conditions themselves have initially generated, as their own condition of existence, the proliferation of a multitude of new production processes or tasks, which are not mechanised, at least in their earlier stages (e.g. the assembly, testing, and packaging of the electronic micro-components needed by the development of robotised and computer-aided systems) (Henderson 1989).[12]

The upshot of all these material transformations in the capitalist labour process, has been an increase in the internal polarisation of the global collective labourer according to the type of productive attributes that its different members embody. As a concrete expression of the inner nature of the process of capital accumulation, these social processes have been *global in content* and *national only in form*. More specifically, this growing differentiation in the productive attributes of the collective labourer of large-scale industry has been at the basis of the emerging patterns of differentiation of national and regional spaces of accumulation in the last four decades. In effect, based on these productive changes and the revolution in communication and transportation methods, capital, globally, has been increasingly able to disperse the different parts of the labour process according to the most profitable combinations of *relative* costs and productive attributes of the different national fragments of the worldwide collective labourer (through their impact upon labour productivity and unit labour costs), thus giving birth to the NIDL.

The constitution of geographically dispersed 'global chains of production of surplus-value' certainly *started* with the relocation of simple manual labour processes (especially those of modern manufacture in the sense defined above), while concentrating its increasingly more complex parts in advanced capitalist countries. This is the particular initial manifestation of the NIDL that Fröbel and his colleagues rightly (though one-sidededly) captured in the late 1970s, without being able to uncover its general content. In fact, the very origins of the NIDL can be traced back to an even earlier period, to what one might call its phase zero. In this ‘primitive’ stage, roughly spanning from the 1950s until the late 1960s, the NIDL mainly emerged in either relatively mature industries, which were not the key material carriers of capital’s production of relative surplus value (e.g. garments and footwear), or in those sectors that, at this stage, were only the precursors of the technological microelectronic revolution that would erupt and spread over the following decades (e.g. simpler consumer electronics, such as the transistor radio in Japan) (Iñigo Carrera 2013: 67). This international fragmentation of production processes gained momentum in the second half of the 1960s and into the following decade, when it accelerated its expansion into what would become key technological sectors, such as the fabrication of more advanced semiconductor devices based on integrated circuits (Henderson 1989: 50–5). Indeed, one could say that these early manifestations of the NIDL constituted its determination as a historical *presupposition* of the latest microelectronics technological revolution which characterises the current phase of large-scale industry proper. But the plenitude of its potentialities could only come about as a historical *result* of the leap forward in automation through the computerisation and robotisation of the labour process. In these more developed forms, the NIDL would expand to a much wider array of sectors.

Thus, the emergence of the NIDL was originally guided by capital’s search for not only relatively low wages, but also domestic working classes whose specific productive attributes included the habituation to ‘intensive, collective and disciplined labour’ (Iñigo Carrera 2013: 66) under harsh conditions (otherwise, it could plausibly be argued that most countries in, say, Sub-Saharan Africa would have been actively integrated into the NIDL instead of virtually being turned into reservoirs of consolidated relative surplus populations). This has actually been the case for domestic working classes with a genesis in wet-rice cultivating societies, like those of East Asia (Grinberg 2014: 9).[13] Indeed, before being incorporated into the active industrial army, those national fragments of the global working class had formed a *latent relative surplus population* composed of formerly free peasants who were nonetheless subordinated to a centrally and hierarchically structured tributary system of exploitation (Iñigo Carrera 2013: 66). Therefore, it follows from this that the possession of a cheap domestic labour force that suited the emerging material requirements of the accumulation of capital on a global scale was not simply one factor among others. In reality, it was the *decisive* East Asian institutional specificity underlying its successful industrialisation process. Certainly, this process has taken shape through the consolidation of particular national state policies quite accurately described in great detail by, so-called, statist scholars in the debates over the nature and features of 'late development' in East Asia (Amsden 1989; Wade 1990). But, as pointed out above, those policies did not *determine* the form nor the potentialities of the accumulation process in that region; they only *mediated* the creation and subsequent reproduction of the necessary conditions to accumulate under that new specific modality. These have included: export promotion; liberalisation of imports of inputs used in export activities, as far as trade policies were concerned; and, in the area of industrial policy, the achievement of the extremely accelerated concentration and centralisation of private industrial capital required for world market production (or, when necessary, for the direct concentration of industrial and/or banking capital under state ownership) (Grinberg and Starosta 2009: 772–3). The need for such a rapid concentration and centralisation of capital, in particular, meant that those processes could not be left in the hands of the free will of individual capitalists and had to be imposed upon them by the capitalist state in the form of indicative planning, the preferential allocation of credit tied to export targets, competition rationalisation, and so on. But, above all, these so-called developmental states had in all cases the political suppression of independent labour movements as a fundamental content of their policies (Deyo 1989).

Now, as Marx already emphasised in *Capital*, large-scale industry's technical basis is revolutionary and 'never views or treats the existing form of the production process as the definitive one' (Marx 1976: 617). This generic feature of this material form of the production of surplus value has been potentiated by its microelectronic-based automation, which has led to a period of accelerated technical change. As a consequence, the technological support of the NIDL has experienced a permanent process of reconfiguration which, far from undermining the latter, has constantly renewed its basis and actually made possible its expansion into ever-newer sectors. In effect, as skill-requirements become revolutionised with each step forward in the automation and/or knowledge codification process, each of the organs of the collective labourer can be relocated into different countries according to the optimal combination of relative costs and productive qualities of the labour-power available in each national space of valorisation. In this sense, although as mentioned above the NIDL initially centred on the relocation of the valorisation process in 'unskilled-labour-intensive' industries, like clothing, footwear and, crucially, microelectronics assembly, its subsequent *immanent* dynamics have led to its extension into an ever-wider range of industrial sectors, including relatively complex ones, such as steel, automobile, and microelectronics production (Grinberg 2014: 10). Moreover, these very technological developments eventually made possible the international fragmentation of the productive subjectivity of the different *intellectual* organs of the global collective labourer, as many of these scientific and creative productive functions also experienced a process of *relative* 'de-skilling' (Huws 2014). But this evidently presupposes the further expansion of the productive subjectivity of wage-labourers responsible for codification of that knowledge that can be now transferred elsewhere and that of those responsible for managing, when necessary, the direct productive co-operation of those geographically dispersed partial organs of the collective worker. And this more highly scientifically developed labour-power tends to remain based in 'advanced industrial countries' (at least to date) (Iñigo Carrera 2013: 79). The NIDL thereby has extended its reach into the realm of scientific and technological development, that is into intellectual labour.

Thus, as local peasant surplus populations in the most advanced East Asian economies were exhausted (first in Japan and then in the first generation Asian Tigers), domestic working classes began to be reproduced under new conditions which, in turn, have enabled them to perform the increasingly more automated and/or complex labour-processes entailed by the expansion of the NIDL into ever-renewed industries and/or productive functions (Grinberg 2014: 10). These transformations of their productive subjectivity have been necessarily *mediated by* the educational and R&D policies of the respective nation-states. However, the successful industrial upgrading of those countries was not simply determined by the implementation of those policies. In the first place, their 'success' was premised on the prior transformation of the qualitative content of the respective accumulation processes through their active subsumption under the NIDL as renewed sources of cheaper and equally disciplined labour-power. In the second place, it was also premised on the prior development of *skill-replacing* technical change in certain sectors of social production and/or the increase in the value of Japanese labour-power.

Although this necessarily meant that real wages tended to rise (since the greater complexity of labour-power entails that its value must be higher), that the workers' movement strengthened, and that the class struggle intensified in these countries (since the rise in real wages cannot simply result from the pure automatism of the market but must be mediated by the organised political action of wage-labourers as a class), East Asian working classes continued being *relatively* cheaper for, and more submissive to, capital vis-à-vis the working classes in the more advanced capitalist countries. Note, however, that this industrial upgrading of the first generation of East Asian late-industrialising countries was generally possible *after* the introduction of technological changes that comparatively decreased the complexity of labour-power needed to perform the respective productive tasks (Balconi et al. 2007: 842). On the other hand, as soon as a particular national working class became too expensive (which tended to occur as their productive subjectivity, and hence the value of labour-power, progressively lost *almost* all trace of their peculiar peasant origin and became a genuine product of large-scale industry), capital started to relocate the simpler forms of labour-power to other countries which offered new similar sources of cheap and compliant labourers. Production in 'unskilled-labour-intensive' industries contracted in these countries, while it expanded in others where surplus populations of peasant origin were still extensive and real wages lower (e.g. Malaysia, Thailand, Indonesia, Mexico, and China) (Grinberg 2014: 10).[14]

The global total social capital has used this reconfiguration of the international division of labour to multiply the differentiation in the conditions of reproduction of the various segments of the collective labourer of large-scale industry on a world scale. Yet, as previously mentioned, this general global transformation in capital accumulation took concrete shape not only through changed patterns of *national* differentiation, but also *within* the latter and through the formation of wider *supranational* or *regional* spaces of valorisation, whose constitution thereby required the mediation of the development of novel international juridical and political forms (e.g. the European Union, EU—see Chap. 7). In this way, the divergence in the conditions of reproduction of the expanded and degraded organ of the collective labourer could occur inside advanced capitalist countries themselves. This process was, however, more difficult and drawn-out. The very material and social forms of the production of relative surplus-value prevailing during the prior historical cycle of accumulation constituted a barrier that needed to be uprooted before the aforementioned multiplication of the internal differentiation of the collective labourer could take place.

In effect, the so-called Keynesian phase of capitalist development was based on the relatively undifferentiated reproduction of the two general types of productive subjectivity, that is expanded and degraded. This had a twofold material basis. On the one hand, both kinds of subjectivity involved a certain degree of universality in the materiality of their productive attributes. This is obvious in the case of the expanded productive subjectivity, insofar as its increasingly scientific form aims at the conscious regulation of the universality of the movement of natural forces. But we have seen above that even the degraded productive subjectivity of large-sale industry requires the development of a labour-power with certain universal capacities before its exertion in the direct production process. On the other hand, however degraded the subjectivity of direct labourers was during this phase of capital accumulation, it still retained a strategic productive intervention at the heart of the production of relative surplus-value, that is in the production of machinery itself (Iñigo Carrera 2013: 61ff). In effect, both the calibration of machinery and the assembly process still depended on the subjective expertise of direct workers. This strategic intervention gave the degraded organ of the collective labourer a particular source of political strength in the struggle over the value of labour-power, which allowed those workers to force capital to moderate the differentiation of their conditions of reproduction vis-à-vis those performing more complex forms of labour. Under those circumstances, it was cheaper for the total social capital to socialise at least part of the reproduction of the working class through state-provided education, health, and so on, in order to produce universal workers on a mass scale. This is the essential content behind the development of the welfare state. Furthermore, this was not a merely an economic process that came about through the pure automatism of market forces, but it took necessary concrete shape in the political unity and increasing strength of the working class vis-à-vis the bourgeoisie in their struggle over the conditions of their social reproduction (see, for example, Clarke 1988: Chap. 10).

In order to spread the accentuated differentiation of the conditions of reproduction and exploitation of the varied organs of the collective worker within advanced capitalist countries, capital thereby had to break up the unity that the working class had achieved as an expression of those determinations of the prior historical cycle of accumulation. The very dynamics of the unfolding of the NIDL, mediated as they were by the general crisis of overproduction of capital on a world scale that exploded in the mid-1970s, provided the means by which such a process of restructuring could push forward (Iñigo Carrera 2013: 70–4). In the first place, in eroding the need for the strategic manual intervention and/or practical knowledge of direct labourers in the production process of machines, the microelectronics-based automation of the labour process at the basis of the development of the NIDL undermined the material source of the political power of this segment of the working class. This situation was further compounded by the real or potential shift of the valorisation process that, as we have seen, this technical change made possible. In the second place, working class solidarity was weakened even further through the disciplinary effects of the growth of the relative surplus population in most advanced capitalist countries, brought about by the open manifestation of the said global crisis of overproduction (whose definitive resolution has been postponed ever since through successive cycles of credit-fuelled expansion) (Iñigo Carrera 2013: Chap. 6). Thirdly, the concomitant crisis of 'national developmentalism' in the Global South also swelled the ranks of the relative surplus population, which, in turn, provided the source for a massive increase of migratory flows into advanced capitalist countries (Ceceña and Peña 1995). As already mentioned, this politically regulated international migration allowed capital to superimpose the formal mediation of national citizenship on the differentiation of the conditions of reproduction between the two general kinds of productive subjectivity *within* the borders of advanced capitalist countries. Finally, it should be obvious at this stage of our argument that the economic and/or political integration of national spaces of valorisation into broader free trade areas (for example, the NAFTA, North American Free Trade Agreement) or regional political community (for example, the EU), has been yet another concrete form in which capital achieved the increased heterogeneity in the reproduction of the varied organs of the global collective labourer.

In sum, as a result of its own immanent tendencies, the simplest original form of the NIDL has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the diverse past histories of the different national fragments of the working class (through their impact upon their general conditions of reproduction and condensed in the, so-called, historical component of the value of labour-power). Each country that is actively subsumed under the NIDL therefore tends to concentrate a certain type of labour-power of distinctive material and moral productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital as a whole in the least costly possible manner. In this way, capital has fragmented the reproduction of the different productive organs of the collective labourer so as to pay for each individual kind of labour-power *only* (or as near as possible to only) that which is strictly necessary for the most immediate reproduction of that labour-power's relevant material and moral attributes. Crucially for the purpose of the general argument developed in this book, this different constellation of the global accumulation process does not involve the *transcendence* of the NIDL, but represents a more complex *form* assumed by the same general *content*, namely, the international fragmentation of the productive subjectivity of the global working class. Its general developmental dynamics have been nicely and succinctly captured by Grinberg (2011: 35), who argues that productions in specific industrial sectors has thereby expanded in some countries while contracting in others where new and more advanced sectors developed, following a rhythm determined by the evolution of those two main factors—that is, material changes in the capitalist labour process and relative cost and productive attributes of national labour forces (see also Silver 2003).[15]

Conclusion

This chapter has offered a revision of the original NIDL thesis that, I think, can account for the apparently more variegated recent trajectory of the world economy and, therefore, which can avoid many of its shortcomings. In order to do this, I reframed the insights found in Fröbel, Heinrichs and Kreye's contribution in an alternative approach to the relationship between the worldwide unfolding of the Marxian 'law of value' and 'uneven development'. More specifically, this approach posited the production of relative surplus-value through the development of *large-scale industry* as the driving force of the essentially global dynamics of capitalism.

On this basis, I have identified the main tendencies and transformations in the global process of capital accumulation since the 1960s, arguing that their *novel* features have certainly revolved around the constitution and subsequent development of the immanent dynamics of the NIDL. However, I have also noted that, contrary to the over-generalisations of the early formulations of the NIDL thesis, this modality in the material articulation of the global accumulation process has not led to the sheer *disappearance* of the, so-called, classical international division of labour. Indeed, as the subsequent case-study chapters in this book by Purcell, Fitzsimons and Guevara, and Grinberg make clear, it has been the continued reproduction of this long-standing pattern of differentiation in the world economy that explains the developmental potentialities of the accumulation process of most Latin American countries in the Southern Cone, both their stagnation since the mid-1970s up to the early 2000s and their recent boom in the last decade fuelled by the hike of international prices of primary commodities (Grinberg and Starosta 2014).

By contrast, the argument showed that the initial rise and more recent upgrading of East Asian industrialisation, which has been often used as evidence against the original formulation of the NIDL thesis by Fröbel, Heinrichs and Kreye, has actually responded to developmental patterns firmly rooted in the key social processes associated with it, namely: the potentialities created by contemporary forms of microelectronics-based automation; and the large local availability of relatively cheap, highly disciplined, and easily trainable working classes. However central to the long-term development of the East Asian countries, state policies did not *determine* their industrial success. They only acted as a necessary national political mediation of social processes grounded in the wider transformations of the global production of relative surplus-value by the total social capital.

More broadly, the central underlying implication of this chapter's contribution is fundamentally methodological, and concerns the inner connection between what outwardly appear as two sets of differentiated aspects of capitalist production: the economic and the political; and the global and the national (Grinberg and Starosta 2014). In a nutshell, the approach developed here takes the immanent unity of the capitalist world market as the starting point of the investigation. In this view, changing patterns of *national* differentiation should be seen as expressing the contradictory determinations of the essentially *global* unity of the accumulation process. In turn, the specific *political forms* prevailing in each country (that is, class struggle and state policies) should be grasped as the necessary mode of existence and motion of the *economic content* of capital accumulation. These relations are not grounded in the abstract general principles of 'structuralist' methodology. Instead, I think that they follow from the most general determination of capitalist social relations discovered by Marx through the critique of political economy; they entail the subsumption of the productive powers of the global collective labourer to the autonomised movement of the alienated product of their social labour. Such is the fundamental content of the self-expansion of capital on a world scale.

Notes

1. This, however, begs the question of why one or the other form of the international division of labour tends to prevail in a particular country or region. I think that neither Fröbel, Heinrichs and Kreye nor their critics offered a convincing answer. As Grinberg and Starosta (2009) argue, the existence and reproduction of those protected domestic markets have historically required the continuous inflow of an extraordinary mass of social wealth which complemented the surplus-value extracted from the domestic working class to the point of marking the very specificity of the accumulation process in those national spaces (see also Chaps. 2 and 3). The availability in some countries of an abundant mass of ground-rent, deriving from the presence of exceptional non-reproducible natural conditions in agriculture, mining and/or energy-production, has provided such an additional source of social wealth.
2. Besides, it should be noted that the 'relocation back north' line of reasoning relied on what has been convincingly shown to be a mythical story about the effects of new flexible technologies on the productive attributes of direct workers (Tomaney 1994).
3. This was grasped by Fröbel, Heinrichs and Kreye to a certain extent, although mentioned mainly in passing (see, for instance, Fröbel 1982: 538). In a subsequent study on export processing zones, they explicitly considered the debates on the effects of new technologies on the NIDL and correctly recognised that 'innovations in process technologies have not led firms to turn their backs on low-cost sites in the world-wide organization of their production', since the 'wage-differential' between 'North' and 'South' for the more skilled work often required could be even greater than that between wages for unskilled workers (Fröbel et al. 1987: 15).
4. As we shall see in Chap. 6, these dynamics of relative simplification and a subsequent international relocation of intellectual labour are also at the basis of the Celtic Tiger phenomenon, with software development as one of its emblematic sectors.
5. International migration is thus part and parcel of the NIDL and not its refutation (as implied, for instance, by Cohen 1987). Sassen (1988) offers a more balanced view.
6. In this sense, data on FDI cannot empirically settle the question about the validity of the NIDL thesis, as some authors argue (for example, Kiely 1995: 94).
7. See Jacobson et al. (1979), Walker (1989) and Liokadis (1990), for diverse critiques of the world-system/dependency theory leanings of Fröbel, Heinrichs and Kreye's account.

8. For further elaboration of the determination of capital as the alienated total social subject of the movement of modern society (and hence the inverted social existence of human beings as its personifications), see Starosta (2016).
9. This mistaken focus on manufacture instead of *machino*facture was accurately picked up by Jenkins (1984) in his early critique of the NIDL thesis, although he did not explore the implications of this confusion any further.
10. See Balconi (2002) on this twofold effect of new technologies on the skills of direct labourers. This general contradictory development of the particular and universal dimensions of labour-power subsumed to large-scale industry had already been identified by Marx as its characteristic form of motion. See his discussion of education clauses of the Factory Acts in *Capital* (1976: Chap. 15), and also Starosta (2011).
11. As for the, so-called, polyvalent worker, it has been amply demonstrated that its development might not entail any vertical expansion of skills. Instead, it has involved in most cases the horizontal incorporation of additional, quite simple tasks, that is the sheer intensification of labour (Elger 1990). Rather than being an obstacle, the generally weaker and more compliant working class in certain 'peripheral' countries might have been even more suitable for the greater labour intensity allowed by flexible production methods. This has been noted to be true of Japan as well, one of the hidden secrets behind its competitiveness vis-à-vis American and Western European capitals in the 1980s (Dohse et al. 1985).
12. Strictly speaking, the multiplication of the surplus population relative to the needs of the accumulation process has also constituted a transformation of productive subjectivity produced by the automation of large-scale industry (see Marx 1976: 553–75).
13. As Grinberg (2014: 2) points out, wet-rice cultivation has, among others, the following two characteristics. First, it is highly labour-intensive, notably during planting and harvest periods. Secondly, whatever their extent and complexity and, consequently, degree of centralisation, all irrigation systems have required the 'cooperation at various levels between the farmers in a single water control unit' (Bray 1986: 67).
14. It is this difference in timing that largely explains the divergence in the patterns of industrial development (that is, the extent of the deepening process) between the first generation East Asian Tigers and their 'followers' in South East Asia. Also, many of those later followers had a comparatively greater mass of ground-rent for capital to recover through protected domestic markets before being turned into sources of cheap and compliant labour power for world market production. Thus, it was generally after the collapse of raw material prices (hence of ground-rent) in the early 1980s

that these countries changed their mode of integration into the international division of labour (this also applies to the case of Mexico in Latin America). This, of course, does not mean that the industrialisation process in East Asia simply responded to the dynamics captured by the 'flying geese' thesis (cf. Kasahara 2004). Indeed, the NIDL has taken shape in a hierarchical structure (Bernard and Ravenhill 1995) which, due to global-scale requirements of different types of labour-power, narrows at the top and widens at the bottom. Moreover, the advent of China, with its 'unlimited' supply of relatively cheap and disciplined labour-power, has strongly restricted the upgrading possibilities of the rest of the followers.

15. As Grinberg (2011: 35) points out, the 'flying geese' theory reflects only the second of these factors. Moreover, this theory does not explain why industrial production for world markets using a relatively cheap and disciplined unskilled of labour force could develop in Japan in the first instance.

'Post-neoliberalism' in the International Division of Labour: The Divergent Cases of Ecuador and Venezuela

Thomas F. Purcell

In recent years global transformations associated with the new international division of labour (NIDL), led principally by the demand for raw materials in China, have breathed new life into forms of development based upon the reproduction of the classical international division of labour (CIDL).[1] Venezuela and Ecuador stand out as two well-known cases of left-populist, or post-neoliberal, regimes that have emerged in Latin America and whose 'revolutionary' projects have been financed by revenue from the export of raw materials.[2] In 2014, the share of primary exports as a percentage of total exports was 84 per cent in Ecuador and 98 per cent in Venezuela, signifying that they are both national processes of accumulation into which ground-rent primarily flows.

As Part I of this book has made clear, the CIDL was never simply reducible to the polarisation of an industrialised core and a dependent periphery, the latter restricted to the role of supplier of raw materials and staple foods. Rather, there was an important process of accumulation in the periphery whereby local industrial capital was able to valorise through the appropria-

tion of inflows of ground-rent; a process which today also points towards the continuation of elements of the 'classical' within the 'new' international division of labour (Grinberg and Starosta 2009). Moreover, the continuation and deepening of the CIDL through the rise in primary commodity prices has, somewhat paradoxically, put back on the development agenda the use of income from natural resources for the development of productive forces. It is in this context that the 'post-neoliberal' projects of Ecuador and Venezuela have emerged.

In the recent academic tendency to assess the emergence of left-wing regimes in Latin America by distinguishing between moderate progressive governments (Brazil, Chile, and Uruguay) and, so-called, post-neoliberal variants (Bolivia, Ecuador, and Venezuela) little attention has been paid to the internal dynamics of countries' respective economies. In particular, the latter post-neoliberal variants are often lumped together, either under the notion that natural resources are being used to chart an alternative, welfare enhancing and poverty reducing path in the global economy (Lebowitz 2006; Raby 2006), or that resources are being squandered by profligate macro-economic populists, ineluctably reproducing the 'resource curse' (Bebbington and Bebbington 2011; Weyland 2009). Yet, a central claim of this book is that state policies cannot autonomously shape national processes of capital accumulation. Instead, when national spheres of accumulation are seen as aliquot organs of global capital, state policies can be seen as mediating the realisation and development of the worldwide process of capital accumulation. This chapter argues that even if state policies appear to contradict such unity by pursuing seemingly anti-capitalist development policies, upon closer inspection they reveal themselves as what they are: contradictory expressions of the realisation of capital accumulation rather than a challenge to the forces of global neoliberal capitalism in the name of the people.

With empirical reference to Ecuador's Citizens' Revolution and Venezuela's Socialism for the Twenty-first Century, this chapter argues that—depending upon whether the primary export is of agrarian or mining origin and whether property rights are in private or public hands—the modality, magnitude, and direction of rental appropriation and transfer can differ in significant ways. This turns on Iñigo Carrera's (2007) distinction between agricultural and mining landownership to explain particular national forms of capitalist development and the specific manner in which these are inserted into the global economy. Specifically, the dual landlordism in Ecuador in the form of an agro-export elite and a state-controlled oil sector contrasts with the singular dominance of the state-controlled oil sector in Venezuela. This material basis can be used to explain the manner in which the two national forms of insertion into the international division of labour have determined different national variants of post-neoliberalism.

The chapter is structured as follows. Section one briefly presents Iñigo Carrera's distinction between agricultural and mining landownership. Section two explains the political economy of exchange rate policies and access to foreign exchange in the contexts of dollarisation in Ecuador and extreme overvaluation in Venezuela. By reflecting upon contrasting economic and development discourses, section three asks why Ecuador signed a free trade agreement with the European Union (EU) in 2014, while Venezuela perseveres with the alternative regional trading bloc, the Bolivarian Alliance for the Peoples of our America-Trade Agreement of the Peoples (ALBA-TCP). The chapter concludes with general reflections on the political economy of ground-rent based capital accumulation in conditions of so-called post-neoliberalism.

Different Forms of Ground-Rent and the Social Power of Landlords Within the International Division of Labour

As Part I of this book has already argued, owing to the presence of a vast, irreproducible wealth of natural resources, national processes of capital accumulation in Latin America have been dominated by the export of raw materials. Historically, the insertion of Latin America into the international division of labour played a specific role in the development of global industrial capitalism. By cheapening the means of subsistence and reducing the value of labour power in the new industrial centres, the total global social capital experienced an increase in both labour productivity and the rate of surplus value production (Grinberg and Starosta 2009; Chap. 2). Yet, in order to gain access to non-renewable natural resources attached to such portions of land, capital has historically ceded a portion of surplus-value 'known as ground-rent' (Marx 1981: 755–6). Capital must absorb this loss of surplus-value, so as to not call into question the general social form of landlordism and therefore the very existence of private property (see Chap. 3). Moreover, to the extent that the commodity in question is consumed overseas, this cost is borne by the capital of the importing countries (Iñigo Carrera 2007: 15).

This ground-rent has its basis in natural conditions outside the control of normal capital, that is to say, it is appropriated by landlords who monopolise differential and absolute natural conditions that allow for greater labour productivity in the production of raw materials. Insofar as higher labour productivity is capitalised as ground-rent in the price of production, it is the appropriation or recovery of this extra surplus-value by industrial capital that has characterised the insertion of Latin American raw materials-exporting societies into the international division of labour. However, as Harvey (2005: 70) recognises, 'to the degree that natural resources are unevenly distributed so a certain kind of uneven geographical development results built around conditions of, say, agricultural productivity or the presence of oil reserves'. In fact, the differences between agriculture and mining are key to explaining the development of capitalism in specific countries. We can draw out the implication of this uneven geographical development within and across Latin American societies through an appeal to Iñigo Carrera's (2007: 13–14) analysis of mining and agrarian landownership and the specific capacities of landlords to appropriate differential, absolute, and monopoly rents (Fitzsimons 2014: 137–41).[3]

In general, the ability of landlords to appropriate ground-rent is premised upon the possibility that they could withdraw their lands from production at any moment; however, within this there are two further determinations. The first rests on the difference between the turnover cycles of capitalist production for agrarian and mining landlords. The latter can sit upon a given stock of social wealth (such as oil or minerals), calculating that what they do not appropriate today they can tomorrow, and that in the time in-between the magnitude of rents potentially appropriable will usually increase. This materiality of the mining productive process and the resource itself (which is non-renewable and naturally limited in supply) therefore increases the social power of mining landlords who can withdraw lands from production, thereby determining the marginal lands in the sector (Fitzsimons 2015: 10). For agrarian landlords, however, the decision to withdraw their lands from production can only be compensated for by an increase in the magnitude of future ground-rent. And, as is obvious, the rise in ground-rent due to lower supply will benefit those lands not removed from production. Therefore, in comparison with individual agrarian landlords, mining landlords exercise a relative individual independence in being able to remove their lands from a determined cycle of production and as a way of multiplying monopoly rents (Iñigo Carrera 2007: 13). Unlike the differential portion of the rent, monopoly rent varies not only according to fertility and productivity within the sector, but also according to the monopoly power of landowners relative to the demand from the global economy in general for a limited and non-renewable natural resource.

In contrast to mining landlords, then, agrarian landlords could only sustain monopoly rent on the condition that they restricted the use of their lands *en masse* through an act of solidarity as a class of landholders. It is this particularity that puts before us a second determination:

> by the unity of its content the accumulation of capital is a global process. It is this global unity that is realised by taking the fragmented form of different national processes of capital accumulation, which confront each other antagonistically on the world market. The determination of landlords as a class springs from the global unity of capital accumulation, while their fragmentation into national landlord classes is nothing but the expression of the limits of this class unity in conditions of international competition (Iñigo Carrera 2007: 14, author's translation).

So, for example, if through an act of class solidarity agrarian landlords within a country unilaterally withdraw their lands from production to increase ground-rent, the immediate beneficiaries of this action would be the landlords in the other countries that produce the same commodity. Therefore, should agrarian landowners wish to increase ground-rent on their land it would not be sufficient to count upon national solidarity, but they would have to put their class solidarity to work at the scale at which prices of production are determined—that is, the world market. This is because differential rents spring automatically from competition established between agrarian landlords, whereas monopoly rents can, in part, be put into action through conscious class action—in organisations such as the Organisation of Petroleum Exporting Countries (OPEC). Therefore, when organised as a class at the world market level, mining landowners will have more bargaining power than agrarian landlords *vis-à-vis* industrial capital, making the monopoly rent of mining landlord states—including oil landlord states—much larger (Grinberg 2010).

In addition to the different modalities of differential, absolute, and monopoly rent formation between mining and agrarian landowners, an added social determination is that mining lands tend to be held under public ownership as a means of ensuring that the state earns a net income higher than oil extracting and refining capitals—a pattern set by Venezuela's 1943 Hydrocarbons Act.[4] In contrast, agriculture has historically developed under the control of large private landowners (*latifundios*) and the intervention of the state has largely been restricted to measures such as export taxes and currency overvaluation to divert a portion of the ground-rent away from landlords (see Caligaris, Chap. 3).

The remainder of this chapter argues that the difference between agrarian and mining rents can explain the contrasting concrete political forms taken by state-policies in Ecuador and Venezuela. The difference between the two raw material-exporting countries is not simply due to a quantitative relation (an empirically intractable problem) determined by the type or magnitude of ground-rent, but is also related to the qualitative differences determined by the materiality of the raw material in question. The commonality is that state policies are always the vehicle that channels ground-rent towards industrial and commercial capital through a combination of exchange rate policies, export and import taxes, domestic market protection, price regulation, public subsidies, and state spending (Iñigo Carrera 2007). The following two sections explore specific aspects of exchange rate and trade policies in a comparative empirical context, to show how forms of landlordism and their respective insertions into the international division of labour have determined different national variants of post-neoliberalism in Ecuador and Venezuela.

The Political Economy of Exchange Rates and Natural Resources

The original insertion of both Ecuador and Venezuela into the international division of labour was founded upon the export of cocoa and coffee (Chiriboga 1978; Pérez Sáinz and Zarembka 1979). Inflows of differential ground-rent permitted the formation of an incipient national banking sector, the emergence of wage labour relations, and the embryonic development of internal markets. When in the 1930s the price of raw materials fell precipitously, the Ecuadorian state devalued the national currency, along with most other Latin American exporting states in an attempt to stabilise revenues and support agrarian exports, before embarking upon a shallow form of import substitution industrialisation (ISI) (Maiguashca and North

1991). However, in Venezuela the discovery of large oil deposits fifteen years earlier and the massive rise in exports provoked a revaluation of the national currency by 64 per cent, relative to the US dollar, in the period 1929–1938 (Hein 1980: 232). This led to the structural decline of agriculture as export prices became 'laughable', failing even to cover costs of production (Alberto Adriani, cited in Baptista and Mommer 1987: 12). It specifically spelled the end of the predominance of coffee and cocoa as the commodities that articulated the link between the Venezuelan national process of accumulation and capital accumulation at the world scale (Pérez Sáinz and Zarembka 1979). Therefore, while in Ecuador the predominance of agro-exports demanded a devaluation of the national currency, in Venezuela devaluation was seen to be more harmful to the economy than the potential gains from reactivating traditional agricultural exports—especially since a devaluation would favour foreign oil companies (Baptista and Mommer 1987).[5]

This juncture is worth revisiting here in order to historically locate the roots of exchange rate dynamics and vested interests that today influence the concrete political forms of post-neoliberalism in Venezuela and Ecuador. More recently, in the former, strict exchange rate controls were imposed to prevent capital flight during the failed business strike in 2002–2003, pegging the new *bolívar fuerte* (BsF) at an overvalued rate of BsF 1.90 to the US dollar (USD) and requiring applications to the specially created foreign exchange commission, Comisión de Administración de Divisas (CADIVI), to access dollars. In Ecuador, a financial crisis in the late 1990s and intense lobbying by the agro-export elite saw the abandonment of the *sucre*, as the economy was officially dollarised in 2000 at an extremely undervalued rate of 25,000 *sucres* to the dollar, hitting small national savers hard but reducing internal private and public debt (Gastambide 2010: 351; Ruiz Acosta and Iturralde 2013: 69). These exchange rate politics have given rise to distinct *rentier* social relations: in Venezuela, one that revolves around an oil landlord state in conditions of extreme currency overvaluation; in Ecuador one that revolves around a dualism between an agro-export elite and an oil landlord state with limited control over monetary policy.

It is estimated that during the Chávez government in Venezuela (1999–2013) exchange rate overvaluation—understood here as a deliberate state policy rather than the unintended impact of windfall revenues as argued by theorists of the 'Dutch Disease' (see Corden and Neary 1982)—remained higher than 200 per cent to the US dollar and has reached peaks of 400 per cent (Kornblihtt 2015). Despite five devaluations since the creation of the CADIVI in 2003, the 2015 USD exchange rate of BsF 6.3 (now administered by the National Centre for Foreign Exchange) was overvalued by almost 500 per cent when measured against the parallel 'real' market USD exchange rate of BsF 37.75 (Kornblihtt 2015).[6] The Venezuelan private sector only generated around two per cent of the foreign exchange that enters the country, but a huge dependence upon imports meant that the 98 per cent of foreign exchange generated by the state (through the state oil company PDVSA) was later sold at a fraction of its real value to a national importing capitalist class (Lozada 2013; Weisbrot 2014).[7] This overvaluation means that persons exchanging national for foreign currency receive a greater quantity of social wealth than if the exchange were at parity. For example, USD100 obtained through the official rate costs BsF 630, while the same amount sold on the parallel market generates BsF 3775, making the parallel market dollar six times more expensive.[8] This has given rise to an almost systematic process whereby groups able to import goods through the official overvalued rate profit handsomely from the appropriation of ground-rent, by selling at the parallel rate—despite state price regulation and severe sanctions against speculation. This brief synthesis illustrates what underlies the price speculation, hoarding, and heightened social tensions that have erupted in Venezuela since 2014.[9] Amidst endemic corruption and growing shortages, but with public opinion firmly against a drastic devaluation of the *bolívar fuerte*, calls have been made to nationalise all foreign commerce (Ellner 2015; Sutherland 2015).

In contrast to the situation in Ecuador, explained below, for the majority of the Bolivarian Revolution—and at least up until 2014—the Venezuelan state has easily financed its imports and has not faced substantial balance of payments problem, recording substantial current account and trade surpluses in 2013 and 2014 with over USD40 billion in foreign reserves (Weisbrot 2014). However, the plunge in oil prices towards the end of 2014 threw the Venezuelan accumulation process into considerable financial turmoil as the steady flow of dollars dried up. To sustain populist social spending and price controls, the government resorted to the inflationary expansion of the money supply and the restriction of imports. Yet, as foreign reserves dwindled to around USD15 billion (their lowest value since 2003), commentators from both ends of the ideological spectrum are suggesting a likely default in 2016, when USD10 billion worth of the dollar denominated bonds are set to expire (see Hausmann 2014; Sutherland 2015). Thus, with inflation nearing 200 per cent towards the end of 2015, it remained to be seen whether the government of President Maduro would devalue the drastically overvalued *bolivar fuerte* as a means of confronting an impending external debt crisis.

In Ecuador—a dollarised economy without the capacity to print or devalue its currency—concern has been rising about the non-oil trade deficit, which reached USD9 billion (9.7 per cent of GDP) in 2013, and an overall trade deficit of USD1.088 billion.[10] Therefore, although it is evident that ground-rent finances imports in both countries, Ecuador also requires sufficient foreign exchange flows to maintain the balance of payments and to safeguard dollarisation. These flows are dependent upon both state oil policy and the private agro-exports elite. In 2013, the private sector in Ecuador generated 43 per cent of foreign exchange through agro-exports, while the state generated 57 per cent through oil exports (Banco Central del Ecuador 2015). The advantage of this dual *rentier* political economy was evident when the dollar was undervalued on international markets between 2007 and 2008 and Ecuador benefitted from the rare occurrence of high prices for natural resource exports and a competitive exchange rate. This scenario saw both the agro-export elite and the state appropriate a high magnitude of differential rents under a seemingly harmonious cycle of economic expansion, recording 4.2 per cent annual growth between 2006 and 2013 (Unda 2013). However, the sharp appreciation of the dollar on international markets from mid-2014, coupled with the fall in oil and commodity prices, has since revealed the limits of dollarised post-neoliberalism in Ecuador.

In the absence of the ability to manipulate the exchange rate as a mechanism to transfer ground-rent, or to directly influence relative prices and therefore competitiveness, Ecuador has turned to an ad hoc system of tariff barriers, selective import substitution, and export compensation to channel ground-rent to local industrial and commercial capital. For example, in response to currency devaluations by Ecuador's neighbours, blanket tariffs of 21 per cent and 7 per cent on Colombian and Peruvian imports, respectively, were introduced in January 2015—some of the savings from which were to be channelled towards export promotion for national industrial capital in a bilateral move that contravenes the rules set out in the framework of the Andean Community. This is ostensibly part of an industrial development project by the Ecuadorian government designed to 'Transform the Productive Matrix' by promoting 'value added' national industrial and agricultural activity (Ministerio de Coordinación de la Política Económica 2011). However, in practice the demands of safeguarding dollarisation has meant that domestic market protection has been reduced to a strategy of limiting the exit of foreign exchange, rather than a mechanism targeted at productivity-enhancing national development (Ospina Peralta 2015). As we will see in the next section, trade deals and inter-regional agreements also emerge to a large extent out of the distinct *rentier* social relations that are evident in Venezuela's and Ecuador's post-neoliberalism, the former led firmly by political ideology and the latter by economic 'realities'.

Trade and Development Policies

Venezuela spearheaded the creation of ALBA-TCP, first through an agreement with Cuba in 2004 and later with eight other countries, including Ecuador.[11] Becoming one of the signature members of the ALBA-TCP resonated with Ecuadorian President Rafael Correa's official discourse around trade. As he stated upon his election in 2007, one of his 'revolutionary' platforms was to be a new form of 'Latin American integration that would create new organisms to replace mercantilist structures' (Becker 2012: 73). Nevertheless, in contrast to Venezuela, the importance of ground-rent from agrarian and maritime lands has increased for Ecuador over the past ten years as non-processed primary exports, such as bananas, shrimps, tuna, coffee, cacao, and non-traditional exports—for example, flowers—have become crucial sources of foreign exchange. Given that the magnitude of ground-rent available for appropriation is limited in comparison with Venezuela's mono-production economy, for instance, ensuring the competitiveness of such exports is essential to Ecuador. As we will see, for this reason the recent nationalist rhetoric in Ecuador's post-neoliberal trade policy has never reached the same depth of anti-imperialist rhetoric as it has in Venezuela, remaining instead at the level of diplomatic and political posturing over sovereignty.[12] While Ecuador moved to reconcile its agro-export interests within new free trade agreements with the EU—an indication that the magnitude of ground-rent in Ecuador is not enough to sustain import-substitution of any significant kind—the ALBA-TCP has been touted as a 'counter-hegemonic alternative' to (North American) free trade and 'capitalist globalisation' (Muhr 2012).

The ALBA-TCP bloc is structured upon the principles of 'fair and sovereign trade' in the areas of energy, finances, food, education, health, telecommunications, and infrastructure that directly involve eight signature members along with around twenty non-country members that participate in energy agreements and cooperation. The ALBA-TCP has been held up as:

> the first time a country [that is, Venezuela] has used its resources not only for endogenous development, but also for regional development. A new strategic regionalism that breaks, transcends and redefines the traditional parameters of international trade in favour of cooperation, complementarity and solidarity (Aponte García 2014: 19, author's translation).

In a regional context where leftist governments have come to power in a growing number of countries, Venezuela has used accumulated foreign reserves to lend to borrowing states with low creditworthiness—such as Argentina, Bolivia, Ecuador, and Uruguay—at below market rates (Grinberg 2010: 195). And within the ALBA-TCP group, Venezuela has committed USD 250 million for the construction of an Economic Fund for Cooperation and Productive Investment, along with USD1 billion for the emission of a special ALBA bond (Aponte García 2014: 198). The use of such funds has been championed by some as the means by which cooperative—rather than comparative—advantage will support the regional production of 'use-values over capital accumulation' (see, for example, Aponte García 2014: 194–5).

Although defenders of the initiative are keen to counter claims that the whole project rests upon Venezuela's oil wealth, the very strengths of the bloc are cited as its wealth in raw materials generally: the highest reserves of oil in the world; 50 per cent of the world's lithium reserves; the highest reserves of natural gas in Latin America; huge mineral reserves, including iron, gold, coltan, nickel, aluminium, copper, steel; large areas of cultivable land; and biodiversity.[13] This oil and natural resource diplomacy is couched in ideologically progressive notions of alternative production and cooperation.[14] For instance, the ALBA-TCP has established new concepts of productive and business complementarity through bilateral and multistate 'grand national enterprises', 'grand national projects' or action programs, and 'grand national institutes' or research centres—the scale and novelty of which have been enthusiastically celebrated by commentators (for example, Aponte García 2014: 19; Muhr 2012: 233). However, the grand national enterprises in particular reproduce the same normative and voluntaristic logic of national initiatives in Venezuela—such as social production companies (see Purcell 2013: 154)—whose explicitly stated aim is to satisfy social needs by producing use-values outside the 'logic' of capital accumulation. The problem with asserting this latter point is that use-value and exchange-value are not separate forms assumed by goods when subject to social rather than private production, but are distinct determinations of the same object, the commodity. As such, in the capitalist mode of production social wealth does not and cannot 'simply appear as the material accumulation of use-values but, rather, as the accumulation of value' (Iñigo Carrera 2006: 191).

Based upon this materialist reading, the main issue confronting the ALBA-TCP is that the form of wealth which it has at its disposal (that is, ground-rent) would have to be transferred into a form of capital that is able to actively participate in the transformation and development of society's productive forces—that is, into normal productive capital—if it were to engender development. That is to say, if the project could move to concentrate ground-rent at the scale necessary to put ALBA-TCP on a par with world market levels of productivity, but under a social form of regional state-control that redistributes and reinvests to meet the political and social goals of ALBA-TCP, then something other than an integration of 'underdeveloped' landlord states dressed up in ideological platitudes could emerge. Yet in practice, and notwithstanding the regional social and welfare achievements of the ALBA-TCP (see Muhr 2012: 235–6), inter-regional ALBA-TCP trade (aside from oil) is comprised of low-value industrial goods and foodstuffs that only made up around USD 8 billion worth of trade between 2005 and 2011 (Aponte García 2014). As Grinberg (2010: 198) has argued, 'the strong opposition of Venezuela to the implementation of the Free Trade Area of the Americas (FTAA), did not come from the recognition by their political leaders and populations of the policy failures of the 1990s'; instead, 'it arises from the recovery of the amount of ground-rent available for appropriation and its capacity to sustain industrial production for the protected domestic/regional markets'.

Although state policies protecting the national market have also emerged as a fundamental basis for the post-neoliberal project in Ecuador, the dual *rentier* economy therein has limited the ability to completely disavow the international context into which they are inserted. For instance, it has been pointed out that the purported USD1.7 billion in foreign exchange savings in 2013 were less influenced by import substitution measures than by the high prices reached by the export of shrimps, bananas, and cacao (El Comercio 2014). It is in this context that, after years of abstaining from inter-bloc negotiations, in January 2014 Ecuador returned to the negotiating table under pressure from the imminent expiry of the EU's Generalised Scheme of Preferences, which gives developing countries preferential access to the EU market. In the face of severe internal pressures (both for and against), new negotiations culminated in an agreement signed in July 2014. The definitive agreement will not be signed until 2016, when it also has to be approved by the National Assembly and the Constitutional Court. However, the interim deal ensures that Ecuadorean products, such as shrimps, bananas, African palm, and tuna will continue to enter the EU under preferential terms.

Earlier in 2014, Peru and Colombia—Ecuador's main competitors for the export of certain raw materials—had already signed bilateral free trade deals, and had undertaken the currency devaluations discussed above, intensifying regional competitive pressures within the international division of labour. For example, in 2014 the EU entry tariff for the export of a metric ton of bananas from Peru and Colombia was 110 €, whereas Ecuadorean exporters were paying 132 € per ton (CDES 2014). Given that the banana sector is Ecuador's most important export after oil, in terms of both foreign exchange earnings and employment, the importance of this agrarian source of ground-rent finally swayed the decision to sign the deal. In this context, Ecuador was forced to equal conditions agreed by Peru and Colombia, which included: new safeguards for intellectual property rights (on seeds and agro-chemicals); the liberalisation of the entry of capital goods and processed foodstuffs (such as milk and cheese); the lifting of restrictions on EU companies to purchase land and water reserves; the liberalisation of financial services and telecommunications; and the opening up of state contracts and public purchasing to bids from EU companies. This has been interpreted as a form of modernisation that favours pragmatic international trade in the interest of the *rentier-financial*-importing sectors, aligned with the demands of transnational capital (Muñoz 2013: 123). Furthermore, the deal is perceived to protect overwhelmingly the interests of large agro-exporters, intensifying local competition and negatively impacting thousands of small peasant producers. For example, the average production costs of a litre of milk in the EU is less than 27 cents, while in Ecuador the costs are around 40 cents—hence concern that the influx of cheaper milk is likely to bankrupt the many peasant family producers involved in the sector (CDES 2014).

The deal also illustrates the limits of class solidarity among agrarian producers, outlined earlier in this chapter. If Ecuador were to renege on free trade deals and lose markets for its agrarian exports, extra differential rents would flow to competitors whose land in production has a guaranteed market. Coupled with the inability to control their monetary policy so as to undertake a competitive devaluation, which may have offered an exit route from the agreement, Ecuador is locked into the same pattern of exporting raw materials and importing higher 'value added' goods and services.

As this book has stressed, processes leading to the formation of the NIDL have not been static (see also Fröbel et al. 1980), rather they have taken shape in a wide and constantly changing range of combinations of relative cost and productivity characteristics of national labour forces. Taking inspiration from the perceived possibilities inherent in the NIDL and the, so-called, knowledge-based economy, the state in Ecuador has in fact targeted investment toward 'future revolutionary industries such as biotechnology, nanotechnology, bio-electronics, new materials and new energies, socially shaped by the growing environmental awareness and concerns' (Pérez 2008). As it stands, knowledge-based development initiatives have an ideological rather than substantive character, seen for instance in the creation of Yachay—a new high-tech City of Knowledge—that seeks to emulate an 'innovation milieu', characteristic of Silicon Valley, in an old sugar cane hacienda. Meanwhile, free-trade agreements that ensure the future competitive export of primary resources are being rationalised by the government in terms of merely being a short-term measure to ensure inflows of foreign exchange that can fund the take-off of these other knowledge-based public investment strategies.

For different reasons, what the two cases of ALBA-TCP and free trade with the EU demonstrate is that all divisions of labour, whether national or regional, presuppose the international division of labour. As such, any form of protectionism 'amounts to a defence within, not against, the world market. Capitalist social relations are always already world market relations' (Bonefeld 2008: 71). Therefore, the ability of the ALBA-TCP to act as a defence against 'imperialism' or 'neoliberalism' within the international division labour rests upon the magnitude and qualitative origin of mining rents that the Venezuelan oil state can appropriate and transfer. In contrast, Ecuador's dependence upon foreign exchange from agrarian exports means the state cannot risk agrarian rents flowing to their nearest competitors, and the state has therefore defended its free trade agenda with the EU in terms of economic pragmatism.

Conclusion

To understand the divergent political forms of post-neoliberalism in Ecuador and Venezuela, this chapter has developed insights from Iñigo Carrera's distinction between agrarian and mining landlords. Drawing empirically upon examples of the political economy of exchange rates and trade, the chapter demonstrated that the source and magnitude of ground-rent available to finance different development models has a qualitative impact upon the capacity for state intervention. Venezuela's *sui generis* vision of post-neoliberalism, based upon a mono-production economy that generates huge oil rents and transfers social wealth to the rest of society through extreme currency overvaluation, rejects free trade and seeks a stronger model of regional integration based upon claims concerning social justice. To this end, the flagship regional development and trade initiative ALBA-TCP, financed unilaterally by Venezuelan oil rents, has favoured the ideological—rather than substantive—promotion of new concepts of productive and business complementarity, which, it alleges, point to a route out of, and beyond, capitalist relations of production. In contrast, Ecuador's dual dependence upon (public) mining and (private) agrarian ground-rent has tempered the government's radicalism: on the one hand, it has financed a shallow and limited process of ISI under the ideological banner of promoting a knowledge economy; while, on the other hand, it has worked to ensure the continued viability of dollarisation and access to agro-export markets. In sum, this chapter has shown that far from representing an alternative form of development that can resolve conditions imposed by an external international context, post-neoliberalism is predicated upon, and can be differentiated by, forms of the recovery of mining and agrarian ground-rent in raw material-exporting societies.

Notes

1. For data on the primary commodity boom since the early 2000s, relating to demand for raw materials produced in Latin America specifically, see Arboleda (2015: 2).
2. The term post-neoliberalism is widely used as shorthand to describe the policy and rhetoric adopted by left-populist governments across Latin America from the 2000s.
3. See Note 3 in Chap. 3, for a definition of these different types of ground-rent. What is specific about landlords in the petroleum industry is their capacity to determine the location of marginal lands. By restricting pro-

duction and monopoly rents, the latter then forms the basis for the appropriation of further differential rents because the higher price permits capital to invest in lands not previously used in production (Fitzsimons 2014: 141; Fitzsimons 2015: 10). It should be noted that in practice the different forms of rent never exist in isolation (Caligaris 2014); the schematic differentiation made in this chapter does however help to explain distinct concrete political forms taken by state policies when one type of rent *predominates* over others.

4. This was the institutional-juridical means by which the landlord state in Venezuela tried to secure the fullest possible appropriation of ground-rent.
5. By the time Ecuador discovered large oil deposits in 1967 and began large-scale exports in 1972, a small agro-exporting landlord class was well institutionalised as a financial-commercial-*rentier* elite (Chiriboga 1978; Conaghan 1988).
6. Estimates of an equilibrium exchange rate for Venezuela are somewhere around BsF 30 to the US dollar (Weisbrot 2014).
7. Because of the historic magnitude of currency overvaluation in Venezuela, oil has been the only commodity that can pass through the overvalued exchange rate while allowing oil-producing capitals to valorise normally.
8. With interest rates at 15 per cent and annual inflation running at 60 per cent in Venezuela, trading in dollars is estimated to be 50 times more profitable than either saving or investing in productive activities (Lozada 2013).
9. Since the 2002–2003 business lock-out and attempted coup against Chávez, business groups have attempted to use their control of imports as political leverage, inducing shortages and driving up prices to spread political disaffection with the government. Meanwhile, speculation on imports, bribing customs officials, and smuggling goods over the border to Colombia (a phenomenon referred to as *bachaqueo*) have become such lucrative forms of appropriating ground-rent that they have acquired an almost systemic character.
10. This illustrates the tendency for dollarised economies in Latin America to incentivise imports over exports (Hira and Dean 2004).
11. ALBA-TCP member states include Antigua and Barbuda, Bolivia, Cuba, Dominica, Ecuador, Nicaragua, St Vincent and the Grenadines, and Venezuela.
12. Ecuador refused to sign the Andean Trade Preference Act with the US—a stance linked to the right to grant asylum to National Security Agency defector Ed Snowden—and removed US forces from a military base in Manta they were using as a forward operating location in the 'war on drugs' in Colombia. In June 2011, Ecuador was the only country to hold

out over the vote to readmit Honduras to the Organisation of American States following the coup against Manuel Zeyala. In 2012, Ecuador also boycotted the sixth Summit of the Americas in Colombia in protest at the exclusion of Cuba (Becker 2012: 74, 81).

13. See presentation by Alianza Bolivariana para los Pueblos de Nuestra America Tratado de Comercio de los Pueblos, the Food and Agriculture Organization of the United Nations Committee on World Food Security 39, Rome, Italy, 19 October 2012 (available at: http://www.fao.org/fileadmin/templates/cfs/Docs1112/CFS39Docs/SpecialSession/CFS_39_Special_Session_Alba_Food_Sp.pdf, accessed 29 May 2015).
14. Together with Chile and Mexico, which also have market-oriented economies, the ALBA-TCP countries have formed the Pacific Alliance—a regional trade and investment bloc (Lansberg-Rodriguez 2014).

CHAPTER 6

The New International Division of Labour in 'High-Tech Production': The Genesis of Ireland's Boom in the 1990s

Tomás Friedenthal and Guido Starosta

This chapter examines the foundations of Ireland's rapid expansion during the 1990s and offers an alternative approach to those dominating debates that emerged about the potentialities and limits of this idiosyncratic developmental model and its apparently successful integration into the global economy. Whilst neo-classical economists have tended to explain the Irish fast-growing experience in terms of the adoption of a liberalisation and export-led strategy that opened the economy to vast inflows of high-tech foreign and direct investment (FDI) (Barry 1999, 2000; Krugman 1998; Ó Gráda 2002), critical commentators have argued that such an account ignores the active role played by the Irish state, and related institutions and

organisations, in shaping the precise mode in which the 'local' economy integrated into 'globalised networks' of high-tech production and innovation (Ó Riain 2004). According to this alternative view, the Irish case is that of a, so-called, Network Developmental State that manages the connection between the local and the global and, through its active involvement in industrial development, steers the national economy along a path of integration into the technologically most dynamic elements of the world economy. In contrast to the authoritarian 'state developmentalism' of East Asian Tigers, and their (initial) reliance on the 'super-exploitation' of cheap manual labour, the Celtic Tiger model was predicated on its democratic institutions and better qualified, higher-wage jobs in cutting-edge sectors of the economy.

Without disputing the empirical value of many of the *descriptions* offered in the literature, here we take issue with those apparently opposed *explanations* insofar as they both account for the trajectory of the Irish developmental process on the basis of the successful implementation of 'correct' nation-state policies (even if they disagree on the precise nature of those policies). By contrast, this chapter argues that the Irish experience is yet another concrete expression of the further development of the essentially *global* laws of motion of the new international division of labour (NIDL), as explained in Chap. 4. More specifically, it argues that the *particularistic-skill-replacing* technical change that characterises the production of relative surplus-value across the globe has allowed capital to integrate into the NIDL not only national working classes which were materially and morally suitable for the performance of the simpler manual tasks initially required by the micro-electronics revolution, but also those with comparatively more skilled but still relatively cheaper labour-power. Moreover, we show that the very dynamics of the NIDL then made possible its extension into the more intellectual productive functions of the labour process of capitalist large-scale industry, such as software production. Premised on its origins as a source of latent and stagnant surplus population for the global accumulation of capital, the specificity of the Irish national sphere of valorisation has been determined by those two potentialities of the historical unfolding of the NIDL (that is, the subjection of relatively more complex and intellectual productive functions to its laws of motion). We therefore show that the particular state policies and institutions prevailing in Ireland are therefore grounded in this specific form of integration into the NIDL, which they have *mediated* but not *determined* by themselves.

The Historical Presuppositions of Ireland's Subsumption Within the NIDL

As mentioned above, the specific modality and potentialities of the subsumption of the Irish space of valorisation under the NIDL have their historical premise in the forms taken by Ireland's genesis as a nationally-independent territorial jurisdiction. In order to comprehend the origins of the Celtic Tiger, we must first place the process of capital accumulation in Ireland in a long view of its historical development. More concretely, in this first section we take a brief look at the early subsumption of the Irish economy under the capitalist international division of labour, which flowed from its existing links with England. We shall see that the secret of Ireland's developmental path resides in the formation and chronic reproduction of a relatively large surplus population, as a direct result of the unfolding of global capital accumulation; that is, that the Irish working class became essentially redundant for global capital accumulation by the end of nineteenth century, a condition that would stretch, in different shapes, well into the twentieth century.

The Economic Content of the Genesis of the Irish National Space of Accumulation: The Formation and Chronic Reproduction of a Rural Relative Surplus Population

The upsurge of industrial capital accumulation in England during the second half of the eighteenth century (with its concomitant increased demand for food), led to a long-term rise in corn prices which, also bolstered by the Napoleonic wars, caused the price of wheat to double between 1770 and 1810 (Regan 1980: 10). This process had a profound impact on the dynamics of capital accumulation in Ireland. In effect, the sharp increase in corn prices resulted in a widespread shift across the country from grazing to tillage, which brought with it a profound change in the rural social structure. The labour-intensive character of tillage promoted the subdivision of holdings and thus enabled the formation of new familial units that could survive on ever-smaller plots devoted to the subsistence cultivation of the potato.

Thus, an explosive rural population growth ensued in Ireland, intensifying the competition for land and increasing the pressure for a further subdivision of holdings. In turn, this led to an expansion of ground-rent, which would force an increase in tillage area at the expense of subsistence plots in each individual holding (Mulhall 1988: 97). The contraction of the acreage left for the peasantry's reproduction after the rise in rent was facilitated by the increased cultivation of the potato. Since this was both a rotation and a subsistence crop, the tenant's small plot could be split into a part devoted to corn for rent and another for growing potatoes for subsistence. Rural family labour engaging in cottage industry gave that contraction further room to develop. All this obviously implied a systematic extension of the annual hours worked by the rural family. As Breathnach (1988: 122) points out, these developments meant that by 1800 'the Irish economy had become characterised by a much-bloated labour force heavily dependent on what was to prove an ephemeral export market'.

By the time the Act of Union was passed in 1800, incorporating Ireland into the United Kingdom, the country possessed a fairly developed manufacturing industry compared with most European countries (with the exception of England) (O'Malley 1981: 29–30). Non-textile industries experienced growing competition but still managed to stay afloat by means of restructuring on a larger scale to keep pace with their English counterparts (O'Malley 1981: 31–2). However, the further advance of mechanisation, coupled with the definitive phasing out of tariff protection stemming from the provisions set in the Act of Union, heavily impacted on the Irish cotton and woollen manufacturers and many of them shut down permanently during the depression of 1825–1826. Weaving and embroidery of muslin continued in Ulster, but cotton yarn was being increasingly imported. Due to the concurrent development of powered spinning of fine linen yarn, many Belfast cotton mills were able to change over to linen production and escape closure. On this basis, Belfast managed to become a major global location for the development of mechanised fine linen spinning.

These developments dealt a hard blow to the rural poor, who depended upon domestic spinning to supplement their meagre farming incomes (Breathnach 1988: 129–30). The situation was further complicated when a rise in corn prices, which had formerly resulted in the profound changes in rural structure discussed above, returned after the end of the Napoleonic Wars in 1815. To make matters even worse, the decline of domestic spinning in Ireland coincided with the beginning of a secular rise in cattle prices that led to a widespread conversion from tillage back into (export-oriented) grazing lands. The basis of the entire existing rural system was seriously undermined, and it was only a matter of time until it eventually collapsed. As a result, the idiosyncratic Irish emigration trend started to gain momentum and would finally turn into an absolute population decline after the devastating Great Famine of 1845–1848.

If economic hardship had been limited mainly to the textile industries up to that point, further progress in the mechanisation of large-scale industry in the 1870s in Britain and elsewhere spread to the rest of the Irish manufacturing sector (O'Malley 1981: 33–4). And yet there was a notable exception to this general trend toward industrial decline. As Breathnach (1988: 130) notes, the aforementioned constitution of Belfast as a specialised site for mechanised linen production induced the establishment of a supplementary engineering industry and attracted a major shipbuilding sector. The north-eastern city and its surrounding satellite towns thereby became a classic urban-industrial region of the industrial revolution. By contrast, the remainder of Ireland became a location for agricultural production with low labour requirements, namely export-oriented cattle rearing (O'Malley 1981: 39). As a result, this latter part of the country would eventually turn into a vast reservoir of relative surplus population.

Nevertheless, general economic stagnation and decline in the south of Ireland was not the immediate outcome of its industrial crisis. As a matter of fact, the Great Famine was followed by a period of relative prosperity for Irish farming (Mulhall 1988: 98–9). Reversal to pasture due to the change in prices involved a steep fall in the total number of holdings while larger ones actually increased, therefore implying a process of consolidation enabled by the decimation of the surplus rural population through emigration and the famine. Moreover, these very same conditions of capital accumulation in southern Ireland would also form the material basis for the effective abolition of landlordism. Thus, the death knell for landowners started to ring when the agricultural crisis of the early 1880s set in.

In effect, diminishing transport costs increasingly made possible the integration of new national spaces with exceptional natural conditions into the international division of labour as raw-material and agrarian-commodities producing countries.[1] Domestic agricultural prices dropped sharply as a consequence and, just as the earlier rises in corn and cattle prices involved an expansion in the ground-rent available for appropriation in Ireland, this later fall in prices caused it to plummet. This shrinking of agrarian surplus meant that the valorisation of small agrarian capitals and the landlords' appropriation of ground-rent were no longer mutually compatible. So the land question moved to the forefront of the political arena and, as the mostly British ownership of the land turned the Irish land question into a national question, the struggle against landlordism became a struggle for national independence. The outcome of this struggle was: the abolition of landlordism, by way of a series of changes in the juridical relations governing the possession of the land—that is, agrarian reform (Guinnane and Miller 1997); and it would, soon after, result in the partition of Ireland and the emergence of a new national space of accumulation, the Irish Free State, later the Republic of Ireland.

Whereas a certain degree of concentration of holdings mentioned above meant that a novel class of prosperous small agrarian capitalists had already developed (that is the larger farmers, who represented about one-third of the population in 1900, according to Mulhall 1988: 99), this process was far from uniform and co-existed with the reproduction of the pre-existing fragmentation of land holdings into very small plots. In this sense, the abolition of landlordism and the establishment of peasant proprietorship did not do away with previously established patterns of differentiation in the rural social structure (Mulhall 1988: 129). Insofar as the land reform simply transferred existing holdings into outright proprietorship, the resolution of the land question did nothing to uproot the precarious basis for the material reproduction of the great bulk of Irish farmers, who continued to survive on the production of young cattle in tiny holdings for sale to dealers and fatteners elsewhere (Breathnach 1988: 130). Thus, the continued existence of a rural social structure that permitted the reproduction of the peasant through subsistence agriculture constituted an exceptionally large and sustained source of rural *latent* surplus population and determined a relatively low level of wages (which in turn acted as a barrier to mechanisation).

By the time both the land question and independence had been settled, capital accumulation by larger farmers in Ireland was being sustained by a double source of extraordinary social wealth. On the one hand, the remaining (rather minimal) ground-rent available for appropriation in the national space of valorisation, previously captured by the landlord, now flowed to a large extent into the pockets of the farmers. On the other hand, we saw that the prevailing conditions of reproduction of labour-power implied its relatively low value, which in turn entailed an increase in the surplus-value directly extracted by the eastern, larger farmers when employing wage-labour. Additionally, surplus-value was indirectly appropriated in commodity circulation when purchasing the smaller peasants' livestock below its normal price of production for subsequent fattening and re-sale.[2] The agricultural sector was thus the core of the newly independent state's economy, employing 670,000 out of a total workforce of 1.3 million (Kirby 2010: 16).

The Continued Reproduction of the Irish Surplus Population in New Modes of Existence Under a Weak 'Inward-Looking' Industrialisation Process

The decade following independence witnessed the continuity of capital accumulation under these conditions, which included intense and relatively free trade with England (Breathnach 1988: 131). But Ireland entered a *seemingly* different development path after 1932 when a regime of import substitution industrialisation (ISI) was introduced. Domestic industry protection was extensive and the average tariff level was raised from nine per cent to 45 per cent between 1931 and 1936, while tariffs on some goods reached 75 per cent. Non-tariff measures—such as quotas, import licenses, and regulations—were set in place, among which the most important were the Control of Manufactures Acts (1932 and 1934) aimed at securing Irish control of domestic industry. Furthermore, a state bank was established to divert surplus capital into the hands of industrialists, as banking institutions were reluctant to lend even under government guarantee (Kirby 2010: 17).

Here an important point of clarification is needed. As Caligaris's and Iñigo Carrera's earlier chapters flesh out in great detail, this phase of capitalist development geared towards an inward-looking industrialisation process did not actually involve a *qualitative transformation* in the specific modality of the accumulation process *vis-à-vis* the initial agro-export stage. Instead, it entailed the expanded reproduction of the very same mode taken by the overall circulation process of capital, defined by the appropriation of a portion of ground-rent flowing into the national space of accumulation through the export of primary commodities. In this sense, both are part and parcel (strictly, *stages* or *phases*) of the, so-called, classical international division of labour (CIDL).

With respect to all these general features, the Irish experience with ISI hardly differed from similar developmental trajectories elsewhere in the world. But what sets the case of Ireland apart is that, from its very early stages, the limited amount of ground-rent available for appropriation meant that capital had to resort to additional extraordinary sources of social wealth to sustain its accumulation under this specific modality, and in the face of the ever-growing difference between local and world-market production costs. Furthermore, these limitations would also rule out the eventual constitution of fragmented foreign normal capitals (that is transnational corporations, or TNCs) as the fundamental subjects of the appropriation of ground-rent (on this see Chap. 2). Rather, this form of the accumulation process took shape through the proliferation of a multitude of domestically owned small industrial capitals with a very low degree of concentration.

Therefore, this mode of accumulation of capital showed from its very beginning that it had specifically constrained potentialities to unfold in Ireland. Unlike the similar contemporary experiences of the largest Latin American countries (for example, Argentina, Brazil, and Mexico), the more limited magnitude of the extraordinary sources of social wealth sustaining capital's valorisation process in the Irish Republic's national space did not allow for its development beyond a (particularly weak) primary ISI phase, and had very limited capacities for labour-absorption. Thus, manufacturing output rose by just 7.2 per cent between 1932 and 1936, while gross national product at constant prices was only ten per cent higher in 1938 than in 1931, even though industrial employment rose from 110,600 to 166,100 over the same period, suggesting an overall productivity decline (Kirby 2010: 18).[3] Emigration volume fell, in turn, to an average of 14,000 a year over the decade (it had previously reached treble that rate, partly a consequence of the 1930s' world crisis). Furthermore, the inward-looking orientation of new industrial production brought about a 29 per cent decline in exports by 1933, which only recovered their 1930s' volume in 1960 (Kirby 2010: 18).[4] The fairly substantial industrial employment increase (about 40 per cent) over those first years of the new regime was nonetheless insufficient to eliminate the high chronic unemployment that stemmed from the peculiar, and essentially unchanged, Irish rural social structure. In sum: the ISI phase was already facing the immanent limits of its particularly small domestic market in the 1940s; considerable balance of payment problems emerged in the 1950s; while the 1.7 per cent per annum pace of output growth and 0.2 per cent average annual increase in manufacturing employment over the course of that decade caused unemployment to swell; and emigration reached over 50,000 a year, so that between 1946 and 1961 the workforce shrunk from 1,228,000 to 1,053,000 people (Kirby 2010: 19).

In our view, this quantitative evidence expresses the following. The reproduction of the specific content of Ireland's process of capital accumulation during this period revolved crucially around the association between small landholding agrarian industrial capital and small non-agrarian industrial capital over the appropriation of a twofold source of extraordinary social wealth: on the one hand, the remaining (although declining) ground-rent; on the other, and crucially for the purpose of our argument, the extraordinary surplus-value stemming from the peculiar conditions of existence of the Irish workforce, which allowed the cheapened purchase of their labour-power without undermining its normal long-term reproduction. Moreover, given that the magnitude of ground-rent was meagre and actually diminishing, capital accumulation increasingly came to rest one-sidedly on the relative cheapness of Irish labour-power. Those feeble foundations sustaining the accumulation of capital would mean that in less than two decades the widening productivity gap, with normal capital accumulating beyond the national borders, was already confronting the Irish process of capital accumulation with its specific inherent limits. As Breathnach (1988: 132) succinctly puts it, 'Ireland's rather tentative attempt at economic autarky … ran out of steam in the 1950s … at a time when the rest of Europe was booming'.

This idiosyncratic economic trajectory under such a weak ISI process carries a broader significance, whose implications would become apparent in the following decade, as we discuss in the next section. But, for the moment, let us just note that it means that this developmental path did nothing to transcend the general condition of the Irish national sphere of valorisation as a reservoir of surplus labouring population *vis-à-vis* the essentially global contradictory dynamics of capital accumulation. It only meant that the reproduction of the Irish working class as a relative surplus population changed its mode of existence.[5] The only novelty of the ISI phase *vis-à-vis* the earlier reproductive conditions of the Irish working class was that its chronic mode of existence as stagnant surplus population extended beyond the agrarian sector to include its employment by non-agrarian small industrial capitals.

Such were the conditions for the reproduction of capital and the working class in the late 1950s in Ireland. The specificity of the Irish process of capital accumulation was defined by the dominance of small capitals both in agrarian and non-agrarian sectors of industry, whose survival therefore progressively hung upon the purchase of the relatively cheap labour-power of Irish workers, while it constantly produced a permanent outward international migratory flow of the national labouring population. The prospects for the subsequent trajectory of this national space of accumulation did not look very promising. Yet, just as its potentialities appeared to be dwindling (if not, simply vanishing), the global process of production of relative surplus-value started to undergo profound transformations, which would revolutionise the specific form of the Irish process of capital accumulation and breathe new life into its development.

The Emergence of the NIDL and Global Capital's Early Tapping of Ireland's Cheap Labour-Power Reserves in Qualitatively Novel Forms

By the 1960s and through the production of relative surplus-value, which was actually behind the increasing productivity gap between normal capital accumulating in industrially advanced national spaces and small capital accumulating in Ireland, global capital was entering the germinal stages of a thorough revolution in the materiality of the capitalist labour process that would lead to the emergence and development of the NIDL. In its general determination, this emerging re-configuration of the international division of labour would involve the worldwide fragmentation of the different phases of the production process of large-scale industry.[6] Ireland became a very early expression of these novel tendencies shaping capital accumulation on a global scale. This should come as no surprise, given the country's prevailing condition as a reservoir of plentiful cheap wage-workers who, additionally, possessed the necessary productive attributes to be actively incorporated as specific organs of the, now globally dispersed, collective labourer.[7] On top of this essential determination, Ireland also enjoyed a favourable geographical location, in proximity to main industrial and consumer centres, and possessed natural conditions well suited for the maritime transport of commodities. As a consequence, from the 1960s onwards the process of capital accumulation would start to reproduce under a new form. State policies mediating the reproduction of the previous mode of accumulation were consequently dismantled, and were replaced by forms of state direct regulation that channelled the unfolding of the potentialities of Ireland's changed role within the international division of labour.

Ireland had already started to experience a persistent net inflow of foreign capital in the decade prior to the 'opening' of the economy in 1959, which was only partly due to state borrowing under the Marshall Programme.[8] However, the volume of this net capital inflow increased substantially during the following decade, escalating strongly after 1969.

In turn, the specifically outward orientation of capital accumulating under this new basis naturally involved a swift increase in the share of Irish manufactured exports to total exports, which increased from 6 per cent in 1950 to 19 per cent in 1959, and 37 per cent in 1971 (McAleese and Martin 1972). And, given that this surging trend in manufactured exports was essentially *global*, it naturally brought about a thorough reduction in trade restrictions in all major markets, which was nothing more than the establishment of the international juridical forms better suited to mediating the novel specific content of global capital accumulation. From the point of view of the national form of the capitalist state, this implied a new set of external and internal juridical and political regulations.

With respect to Ireland, the transformation of external juridical relations comprised the following measures, among others: the repeal of the Control of Manufactures Acts (which hitherto impeded the foreign ownership of Irish industry) in 1959; the unilateral reduction of external tariffs in 1963 and 1964, enabling the signing of the Anglo-Irish Free Trade Agreement (AIFTA) with the UK in 1966; the extension to Ireland of bilateral rights granting most-favoured-nation treatment by its principal trading partners (under the auspices of General Agreement on Tariffs and Trade (GATT), several years before Ireland became a contracting party in 1967); and finally, Irish integration into the European Economic Community (EEC) in 1973, which resulted in the abolition of the Common External Tariff (CET) on Irish exports by 1978. In the domestic sphere, the economic transformation was mediated by two main state policies: in the first place, grants to export-oriented industries—part of which were conceded only to firms located in rural areas; and, in the second place, a complete remission of income and corporate profit tax on manufactured exports, which was replaced by a ten per cent flat rate on all manufacturing in 1980.[9] Additionally, there were institutional changes within the state, among which the key role and increasing power and organisational autonomy of the Industrial Development Agency as a 'hunter and gatherer' of FDI stands out (Ó Riain 2004: 40). Note, however, that these changed political and juridical regulations were not the underlying *cause* of the new economic forms taken by the accumulation process in the Irish space of valorisation, as most of the literature tends to assume (thereby inverting the form and content of the phenomenon at stake). Instead, they only acted as *necessary mediators*, at the national level, for their emergence and subsequent reproduction, which was actually *grounded* in the transformations originating in the essentially *global* dynamics of the production of relative surplus-value by the total social capital. Indeed, we have seen that the seeds for Irish integration into the nascent modality of the NIDL had already been sown and were germinating by the time the juridical and political forms needed for its effective development first set in.[10]

Normal capital producing commodities for the world market thus flowed into Ireland, seeking the higher profitability attainable by exploiting the fairly well-trained but relatively cheaper Irish workforce in a range of advanced industrial labour processes, which was made possible by new skill-replacing technological changes. The range of sectors that attracted the relocation of capital was initially very varied and included food and milk products, textiles, clothing and footwear, metals and engineering, pharmaceuticals and chemical industries (McAleese 1972: 80). However, it would be fundamentally the electronics, engineering, and chemical-pharmaceutical industries that would act as the main 'drivers' of this reconfiguration of the material basis of capital accumulation in Ireland (Breathnach 1988: 133). 'Phase zero' of the NIDL's worldwide unfolding was taking place, and Ireland was directly involved (see Chap. 4).

Insofar as active participation in the NIDL required that individual capitals reached the necessary scale of operation to be able to compete on the world market, the rapid economic transformation involved precluded its channelling through the valorisation of small capitals that had dominated the Irish economy in the prior phase, since they obviously lacked the requisite degree of concentration.[11] The immediate subject of this process was thereby internationally relocating normal capital in the form of booming inward FDI, which was export-oriented. Indeed, foreign enterprises established in Ireland in the early 1960s exported, on average, 75 per cent of their gross output (McAleese 1972: 79–80). But the specific nature of new foreign capital formation in Ireland is also evident in the diverse origin of FDI and the particular evolution of the distribution of Irish manufactured exports by area of destination (McAleese and Martin 1972: 616–7). Together, the varied composition of origin of capitals (mainly British and German, with some US) and of the destination of their production, rule out the idea that capital relocating in Ireland was driven mainly by proximity and prospects of unrestricted access to the European market.[12] A breakdown of manufactured exports in 1970 also gives us a more detailed picture of the particular production processes in which Ireland specialised by that time. As well as subsectors of the chemical, textile, and construction industries with significant shares in exports, it is possible to observe a strong presence of subsections of machinery production, and especially domestic electric equipment and medical and measuring instruments, in manufacturing export trade (McAleese and Martin 1972: 628–31).

Still, the peculiar pattern of specialisation followed by Ireland in this process of integration into the NIDL was fundamentally determined by its direct participation in the production process of a core element of the novel technological base on which that division would come to rest, namely, computers. Although some (mainly US) electronic component manufacturers had already established plants during the 1960s (Drew and Foster 1994)—in what amounts to early evidence of the international fragmentation of information technology (IT) production—the decision by Digital Equipment Corporation (DEC) to set up a large-scale minicomputer manufacturing operation in Ireland in 1971 is widely acknowledged as a milestone in the Irish IT industry's development. Soon after, five other minicomputer producers and a mainframe manufacturer followed suit and located assembly plants in the country (van Egeraat and Jacobson 2004).

As with the previous wave of FDI in Ireland, the establishment of computer assembly operations was an expression of the international fragmentation of industrial labour processes, albeit a specific one. Indeed, although computers were the material basis for the automation of capitalist large-scale industry, and thus for a tendency towards the elimination of simple direct labour, their own production initially multiplied the need for the latter, insofar as computer assembly and subassembly originally required mostly *relatively* simple productive tasks. Thus, from the very outset the global total social capital tended to locate the simpler portions of the computer manufacturing labour process outside industrially advanced countries. Two main reasons explain why this nascent industry established its assembly facilities specifically in Ireland (and Scotland): the existence of a suitably skilled but relatively cheap workforce; and geographical proximity to user markets, given the rather bulky character of the final product, which entailed significant transport costs. Thus, while the peculiar combination of skills available and wage levels accounts for capital's location in Ireland (and Scotland) rather than in other Western European relatively low-wage countries (such as Spain, Greece, or Portugal), proximity and the kind of exploitable labour-power determined why computer final assembly was not initially located in (and actually was the last computer manufacturing process to relocate to) the East Asian region, where a substantially cheaper and more compliant workforce was being eagerly incorporated by the global total social capital into the active industrial army of labour. Conversely, even at that early stage of the development of the computer industry there were many components that could not be profitably produced in Ireland and which were already being sourced from East Asia, as technical skill requirements were substantially lower and geographical distance was comparatively unimportant given the small size and weight of this type of product.[13]

These tendencies in the evolution of the NIDL in Ireland would continue to unfold with the subsequent technological supersession of the minicomputer by the personal computer (PC) in the following decade. Emblematic landmarks in this industry's trajectory in Ireland were Apple's establishment of a PC assembly plant in 1980, and Intel's decision to locate an advanced microprocessor wafer manufacturing plant, along with PC and motherboard assembly facilities, in 1989. These foreign investments spearheaded a wave of relocations of computer manufacturers into the country, which would lead to a veritable boom in the Irish hardware industry up until the mid-1990s (van Egeraat and Jacobson 2004). However, increasing competition from lower wage countries, particularly from East Asia, struck the Irish electronic components sector, causing many low- and medium-tech component manufacturers to close their plants between 1995 and 1998 and relocate abroad (Barry and Van Egeraat 2008).[14] The increasing substitution of smaller notebooks for bulky desktop PCs in the personal computer market rapidly eroded the proximity advantage and led to the rise of East Asia as a world market site for computer assembly (firstly in Taiwan and South East Asia, and later in China) (Dedrick and Kraemer 2008). This latest technological development in the computer industry would therefore drive Ireland's status as a location for system assembly of PCs into a final decline.

Now, if the rise and demise of the computer hardware industry was not synonymous with the rise and demise of the Celtic Tiger, this could only mean that a novel base for Ireland's integration into the IDL had developed in the meanwhile. As we shall see, this novel base was software production. So Ireland, once a leading location (along with Scotland) for the offshoring of computer manufacturing, became an equally leading world market site for the offshoring of software production.

The Rise of the Irish Software Industry and the Basis for the Celtic Tiger's Boom in the 1990s

The global emergence of a separate software industry can be traced back to the 1950s and 1960s (Dossani and Kenney 2008: 53–4). Its subsequent evolution in the late 1970s and early 1980s revolved around two main lines of development. On the one hand, the material autonomisation of software from hardware and, on the other, the achievement of sufficient production scales for the creation of a distinct software market composed of independent software vendors (ISVs) (Grad 2015). These two mutually reinforcing processes came to fruition in the 1980s. On the hardware side a first key milestone was the successful introduction of the IBM PC in 1981, which combined Intel's microprocessor and Microsoft's MS/DOS operating system (the Wintel standard that would become dominant by the late 1980s), and which resulted in declining hardware prices and an increasing demand for applications. But perhaps more fundamental for the evolution of the independent software industry was the introduction of the workstation in the early 1980s, which was adopted by business users given the limited computing capabilities of the first generations of PCs. The workstation was not only suited to a wide spectrum of business end uses, but also enabled stand-alone programming for mainframes. On the software side a first crucial landmark was the development and universal adoption of the Unix operating system, which combined with the workstation to crystallise in the emergence of the Unix-Workstation (U-W) standard. But what really revolutionised the ISV industry was the development of (and further recoding of Unix in) portable C programming language, which gave rise to Unix/C. In effect, these developments warranted the portability of applications and *system* software (Johnson and Ritchie 1978). Thus, if the U-W standard rendered software *production* platforms independent (because the workstation allowed programming for a whole spectrum of computers), software *products* also attained that status, inasmuch as they could be easily ported to run on very different and rapidly evolving machines. Crucially for the development of the NIDL in the industry, Unix/C programming language opened the doors to a wide fragmentation of the software production process, for it enabled the detachment of system architecture, design, and integration from programming itself, thus rendering the programming component modularised (Dossani and Kenney 2008: 54).

These successive technical revolutions in software production changed the productive attributes that capital demanded from wage-workers involved in its development. In the early mainframe era, a relatively simple (and gendered) division of labour emerged between the *planner*—a highly-skilled, usually male, scientific user—and the *coders*—usually women—who carried out the less complex work (Ensmenger and Aspray 2002). Plain coding initially involved the purely mechanical task of translating a set of instructions or operations delivered to the coder in a language of a relatively higher level of abstraction into a machine-specific numerical (ultimately binary) code. With the development of assembler programmes and assembly languages, this simplest aspect of coding—and therefore of software labour—was fully automated and correspondingly eliminated. This consequently changed the nature of coding, and gave birth to the *programmer*. Inasmuch as assembly language statements usually maintained a one-to-one correspondence with machine language instructions, while the latter varied with the different computer architectures, programming (coding) was now, in its simplest aspect, machine-specific. This required an understanding of the material structure of the machine from the programmer that only *on-the-job* experience could provide. This platform dependency of software was a great obstacle to its development.

The first clear step towards the overcoming of these initial limitations came with the development higher-level languages, whose main conceptual lines of development revolved around formal syntactic notation and formal semantic definitional techniques (Sammet 1972: 607). However, the vast proliferation of higher-level languages signalled that the potential to transcend platform dependency ultimately remained unfulfilled. Programming still involved a great deal of routine manual code-writing and was still very much dependent on an understanding of machine-specific architectures; in other words, it involved a great deal of labour that only a relatively experienced workforce could deliver. These material conditions of software production resulted in the *particularistic*, craft-like character of early programming that was much debated in the late 1960s (Ensmenger and Aspray 2002). In turn, this lack of *universality* in programming labour implied that the necessary productive attributes of the programmer could not be yet developed through a process of formal education.

Under these circumstances a, so-called, software crisis erupted. Essentially, it was a result of the increasing technological gap between accelerating computing capacity and lagging software productivity, so that 'the errors in and cost of writing software tended to grow geometrically with the size of a software artefact' (Campbell-Kelly 1995: 87). Larger-scale projects also clashed with the prevailing subjective, or craft-like, basis of the software technical division of labour. All this led to a series of efforts aimed at the development of the scientific management of its production process, which materialised in, so-called, structured programming during the 1960s and in the discipline of software engineering in the mid-1970s (Mir et al. 2000). Nevertheless, the actual overcoming of these barriers would only result from the further step forward in the automation of software production made possible by the aforementioned development of the Unix-C programming language.

As we have seen, this language ensured easy portability, and therefore resulted in the virtual universality (or platform independency) of the products of programming labour, that is of software. Easy software portability was the outcome of the elimination of a considerable fraction of routine programming labour, known as *porting*. In turn, this was possible precisely because this language succeeded to a large extent in the aspiration that all languages shared, to render programmes virtually independent of the specific material structure of the machines that powered them. This led to the widespread adoption of Unix-C programming language in the late 1970s and early 1980s, which implied that automatic coding by means of a high-level language attained a far reaching universality (Ensmenger and Aspray 2002: 141). Moreover, high-level language programmers were now capable of writing programmes with no knowledge of machine-specific material architectures. In effect, computers controlled by programmes called *compilers* automatically translated the universal instructions spelt out by the programmer into machine-specific codes. Fundamentally, from the point of view of the productive attributes of wage-workers, the upshot of these material changes in the software labour process was that the general skill requirement for the bulk of programmers came down to a command of Unix-C programming language, which *could now* be attained through a process of formal education.

Needless to say, the knowledge of the specific material architecture of computers and components still remained a most important part of software production. However, it became the attribute of newly emerging specialised organs of the collective worker, which was the other side of the general degradation of the productive subjectivity of the programmer. In other words, this technical change entailed a process of internal differentiation of the software collective labourer, now composed of system architects, designers, integrators, and plain programmers. This was largely facilitated by Unix-C structured programming, which, by enabling a more definite separation between conception and execution, allowed the aforementioned modularisation of (plain) programming. In turn, this provided an objective material framework for the development of the technical division of labour and therefore a more solid basis for the development of larger-scale projects that the expanding processing capacity of computers increasingly demanded.

In sum, a particular combination of determinations was in place in the late 1970s and early 1980s that would prove of utmost significance for the 'sudden' emergence of the Celtic Tiger. On the hardware side, the appearance and rapidly-growing computing capacity of the microprocessor meant that smaller, more powerful, and substantially cheaper computers and hardware components could be produced, which became accessible to a wider range of business users. Additionally, the PC was created, opening a new and potentially immense market for computers. This implied, in turn, a huge increase in global demand for software production at all levels. As for software, the appearance of Unix-C programming language emancipated capital from the burden of its dependency on the lengthy on-the-job-learning of *particularistic* productive attributes of programmers, thus opening the door to speedy developments in the newly required universal productive attributes in portions of the existing or future workforce *worldwide*. Software production, a labour process that was at the core of computers (and hence of the NIDL), was itself starting to be subject to NIDL dynamics, in the same vein as hardware production had been a little more than a decade earlier. Economic conditions were therefore ripe for capital to valorise through the exploitation of the adequately skilled but *relatively* cheaper programmer that could be produced *outside* industrially advanced countries. The first steps in the fragmented internationalisation of the productive subjectivity of the collective labourer of software production started to unfold.

Now, inasmuch as both high-level programming language development and software companies with the capability to undertake large projects were mainly of US origin, a fluent command of the English language was an important and general skill requirement demanded from the potential respective organ of the collective worker to be offshored. On the one hand, while high-level languages tended to evolve towards everyday linguistic forms, English was the language of most pioneer developers. On the other hand, we are dealing here with the international fragmentation of a mostly *intellectual* labour process, where the technical division of labour is not *objectively* borne by the materiality of the system of machinery of large-scale industry. Instead, and similarly in this respect to the manufacturing division of labour discussed by Marx, the unity of the collective labourer is based on a '*subjective* principle' (Marx 1976: 501), that is, it has no other immediate material support than the direct relations that its, now internationally fragmented, members are able to establish. As a consequence, their generally direct social co-operation in the software labour process can only be established through a common spoken language. It is regarding other, more *specific* productive attributes that differences between potential locations arise.

Following the laws of motion of the NIDL, as described in Chap. 4, the offshoring of the software labour process certainly started with its simpler tasks, which can be roughly subsumed under the label of plain programming. Although the precise content of the work to be done and therefore the skills required surely differed by type of software, all of them involved a definite (yet varying) amount of those plain programming tasks. But the plain programmer is always an individual member of a team that itself is a collective sub-organ of the (wider) collective worker, whose unity actually establishes the organisation of the respective production process as a whole. The plain programmer is therefore always immediately associated with other more highly skilled software workers. As a consequence, the qualitative and quantitative articulation between these two general kinds of productive subjectivity (that is, degraded and relatively more expanded) determined the specific pool of skills—computer scientists, mathematicians, physical scientists, electrical engineers, systems analysts, programmers, and so on—that global capital demanded in each particular case. The specificities of Ireland as a national space of valorisation, determined as they were by the particular forms taken by its very early subsumption under the novel general forms of the international division of labour, would make it an ideal location in this regard.

As we have seen, Ireland's subsumption under the NIDL in hardware production entailed the presence of a specialised complementary pool of relatively more skilled workers, which was necessary from the very beginning—and was thereafter reproduced in an increased scale through formal education—for capital to exploit the larger, relatively unskilled, and cheaper Irish workforce involved in the initial assembly of computers. Among a broader spectrum of workers trained in scientific, engineering, and technical matters this complementary organ of the collective labourer was largely and crucially composed of individuals trained in electrical engineering, one of the main reservoirs capital would initially draw on to meet the demand for medium-skilled programming labour. Thus, Ireland could provide software-producing capitals with the skills pool that was technically necessary to profit from the exploitation of the relatively cheaper plain programming labour that was the main driving force behind the relocation of capital's valorisation process in the sector. On these grounds, Ireland would become the earliest preferred site for the global relocation of programming labour, which would in turn sow the seeds for the subsequent impressive expansion of the more variegated and dynamic software industry that was one of the key drivers of the prosperity associated with the Celtic Tiger boom during the 1990s.[15]

Thus, as the international fragmentation of software production took off—slowly at first in the second half of the 1970s, but more rapidly during the 1980s—Ireland became the main site for the relocation of a wide range of related labour processes. The activities of foreign (mainly US) companies locating in the country during those years can be divided into the following categories (Sands 2005: 47): (1) *software development centres;* (2) *systems integration, sales and consulting, custom software development;* (3) *software supporting sub-contractors;* and (4) *manufacturing, logistics, localisation, porting, testing*. A closer inspection of the distribution of firms in each category reveals that a broad base of leading TNCs, embracing virtually all different types of software related activities, were already locating in Ireland in the 1970s and 1980s. Thus, although US software product companies such as Microsoft, Oracle, and Lotus did tend to offshore mainly manufacturing, localisation, and distribution functions, there were significant cases of foreign TNCs that appended software development centres to their manufacturing operations, particularly among hardware manufacturing companies (such as Digital and Ericsson), and telecommunications firms (such as AT&T and Alcatel) (Coe 1997: 220–1). Interestingly for our argument, Coe also reports that Ireland would come to be seen as an important UNIX development centre in Europe, with companies such as Motorola and ICL establishing UNIX programming centres (Coe 1997: 220). In our view, this speaks to the fact that the original main driver of the international fragmentation of software production was, fundamentally, the search for cheap plain programming (coding) labour, the simplest but necessary part of any software labour process which, however, must always be technically combined with the corresponding full range of more complex associated skills. As a matter of fact, Coe notes that some kind of dual workforce was being created in Ireland, with two distinct cores: 'one of highly skilled development and localisation staff and one undertaking the less demanding and more repetitive manufacturing tasks' (1997: 223). Later on, this feature would turn out to be crucial for the development of a vibrant Irish indigenous software sector during the 1990s, which became one of the most visible distinguishing marks in debates over the Celtic Tiger phenomenon.

The sample compiled by Sands (2005) also suggests that the distribution of software TNCs in Ireland across those four categories changed during the 1990s, indicating that their FDI seem to have been more concentrated in the last category (that is manufacturing, localisation, distribution), which is also the least skill-demanding category. In effect, although the localisation component involved more skilled work, it represented about 30 per cent of jobs in a typical software firm—half consisting of language graduates involved in translation and the other half of graduate software engineers who actually adapt code for the various national markets (Coe 1997: 222). Yet, this low-skill bias of software TNCs has been to a large extent made up for by the emergence and expansion of a thriving indigenous software sector. Although in the late 1980s it was still composed of very small firms mostly focused on custom software development and other related services for the local market, during the 1990s their strategy changed to product development for export and firms became somewhat larger, but ultimately (despite normal concentration processes) remained small in the main, with the sector thus remaining a highly fragmented one (Sands 2005: 49–53). These smaller-scale operations usually require both low- and high-skilled workers, with the latter generally in a higher proportion *vis-à-vis* larger software development. The dynamism of this indigenous sector has therefore offered a compensatory source of demand for more skilled software labour in the face of the relative skill-downgrade of the more recent wave of relocation by TNCs.

So far our account of the genesis of Ireland's transformation into a Celtic Tiger has placed the accent on the country's integration into the NIDL through its active participation in the computer and software industries, the fundamental carriers of the far-reaching material revolution in the conditions of production that channelled capital's global restructuring of social labour. But those were certainly not the only industries that found in Ireland a convenient national territory for the exploitation of relatively cheap but suitably qualified workers, based on the international fragmentation of the productive subjectivity of the collective labourer.

Notably, an equally dynamic pharmaceutical industry developed from scratch from the end of 1950s and took off during the 1970s. Interestingly for our argument, it followed the same general pattern that governed the overall broader integration of Ireland into the NIDL, namely its participation in medium-complexity portions of industrial labour processes. Experiencing continuous employment growth beyond the 1970s (even after 2001 crisis), the Irish pharmaceutical industry accounted for approximately five per cent of the country's manufacturing employment in 2005, exporting USD17 billion in 2006 (16 per cent of Irish industrial exports and more than a six per cent share of global pharmaceutical exports). The sector's workforce is one of the highest skilled within Irish manufacturing (Egeraat and Barry 2009).

The Irish medical and precision instruments industry is another economic sector that has experienced considerable growth since the early 1970s, as a result of TNCs' increasing tendency to offshore manufacturing activities, in line with the general dynamics of the NIDL (Barry and Bergin 2013). Indeed, by 1970 Ireland's medical and measuring instruments exports already represented a substantial share (about 25 per cent) of Irish total manufacturing exports (see McAleese and Martin 1972: 630–1). According to Barry and Bergin (2013: 326), Ireland is actually 'the second larger exporter of medical products in Europe, after Germany'. Furthermore, it is noteworthy that the share of medical precision and optical instruments in total manufacturing employment in Ireland is quite high (7.9 per cent) *vis-à-vis* the European Union (EU) (2.9 per cent) (Addison-Smyth 2005).

Finally, during the 1990s the country benefited from an important wave of inward FDI in service activities, especially call centres, which has also been an expression of the more recent unfolding of the NIDL through the international fragmentation of back-office work (Breathnach 2000). Crucial factors in this development were Irish relatively low-wages, the existence of a modern telecommunications infrastructure (resulting from a complete overhaul in the 1980s), and the availability of language skills. Indeed, US firms (among which are IBM, Compaq, Dell, Citibank, Hertz, and Oracle) account for 70 per cent of call centres in Ireland and 80 per cent of the sector's total employment, of which a high-proportion (70 per cent) is female labour, and almost a quarter (23 per cent) are foreign workers. By mid-1998, total call centre employment amounted to 6000 persons, distributed in 50 operative centres mainly concentrated in the Dublin region. More broadly, the specific pool of skills demanded from the respective collective labourer also fits into the *general* pattern of Ireland's subsumption under the NIDL, that is, a comparatively high presence of medium-level productive functions coupled with the requisite army of cheap workers bearing a degraded productive subjectivity. As Breathnach (1988: 310) reports, employment in teleservices includes a considerable level of skilled graduate-level work (in the region of 50 per cent), but also a great bulk of routine work requiring lower skill levels.

In sum, we can now appreciate how the Celtic Tiger originated. As a consequence of the very early economic formation of Ireland as a national space of valorisation, the conditions prevailing in the country when the microelectronics revolution started to take shape favoured its pioneer-like integration into the nascent NIDL in a definite set of industrial activities. More concretely, although it also included some traditional sectors, the development of the Irish specificity within the NIDL was especially shaped by the international fragmentation of the pharmaceutical, medical and precision instruments, computer and software industries. These are all industries that demanded a comparatively large proportion of medium- to high-skilled workers, which global capital could find in Ireland at a substantially lower cost than in advanced capitalist countries (yet which were nonetheless geographically close to key European markets), alongside the requisite cheap and disciplined less-skilled work that for technological or economic reasons could not be relocated elsewhere (for example, East Asia). Moreover, all these sectors, along with an incipient international back-office service industry, experienced strong growth in Ireland as an expression of NIDL dynamics, and each one of them contributed to the 1990s boom. However, as for the boom itself, our approach suggests that the peculiar occasion of Ireland's sudden entrance on the world stage as the Celtic Tiger, was fundamentally determined by the explosive increase in global demand for computers and IT products during that decade, as the incorporation of the novel forms of computer-based automation generalised across the globe. Although the new technical basis of the global production of relative surplus-value had already emerged in the early 1980s, the cyclical downturn of the world market in the first years of that decade delayed the manifestation of the accelerated growth of the key driver sectors of the, so-called, new economy. As the world economy resumed an expansive phase during the second half of the 1980s, those sectors took off and actually led the recovery of global accumulation. It is no wonder then that most accounts tend to date the beginnings of the Celtic Tiger phenomenon to 1987, but cannot agree on the specific mix of (externally-related) economic and political factors that changed in those years in order to explain the boom (inter alia: fiscal stabilisation; tax cuts and government-size reductions; social partnership; belated natural convergence inhibited first by protectionism and then by 'poor and wrong-headed fiscal policy'; state policies that raised the education levels of the workforce; an unexplained miraculous sudden growth in export markets and/or inward FDI; competitive devaluations of the Irish pound in 1986 and 1992; the formation of the single European market;, or, lastly, EU structural funds) (see Breathnach 1998; Kirby 2004, 2010; O'Malley 2012). In our view, the reality is that the *fundamental 'structural' underlying causes or determinations* of Ireland's 'Tigerhood' had already been laid out earlier by the specificity of Ireland's subsumption under the NIDL as discussed in this chapter. In this sense, no profound change occurred *circa* 1987. The point is that the cyclical conjuncture of the world economy in the late 1970s and early 1980s meant that the effects of the structural transformations would remain latent for some years. Likewise, we can only tentatively suggest here that the explanation for the *end* of the boom (that is, the transformation of the Celtic Tiger into a Eurozone crisis economy) should also be sought in the twofold dynamics of the further development of the NIDL [the appearance of new competitors with cheaper and more disciplined but adequately-skilled labour-power in key sectors in Central and Eastern Europe and (South-)East Asia], and of the further cyclical development of the long-standing crisis of general overproduction of capital on a world scale.

Conclusion

In this chapter, we have offered a historical sketch of the long-term developmental trajectory of capital accumulation in the Irish national sphere of valorisation. We grounded it in the essentially global dynamics of the accumulation of the total social capital, through the production of relative surplus-value and changes in the modalities of the international division of labour they entailed.

As we have seen, from its genesis as a politically-autonomous national space of valorisation up until the crisis of ISI in the late 1950s, Ireland had been subsumed under the CIDL on extremely weak foundations, which in turn are the expression of a modest and declining flow of ground-rent into the national territory. This led to the constitution of what proved to be a long-standing and resilient determination of Ireland as a reservoir of latent and stagnant surplus population for the needs of global capital accumulation, which would be reproduced under changing historical forms. This determination gives unity to the first great phase of capitalist development in the country.

Premised on this ‘chronic’ historical condition that redounded in the availability of a mass of cheap yet adequately skilled labour-power and a strategic geographical location, the Irish national space of valorisation experienced a pioneering subsumption under the NIDL in the making from the 1950s. These conditions constitute the second great phase of capitalist development in the country, and would give the integration of Ireland into the NIDL an idiosyncratic shape. In the first place, from a very early phase the Irish process of capital accumulation was marked by a pattern of specialisation of its productive structure that revolved around, what was then, a key sector of an emerging microelectronics-based automation of capitalist large-scale industry (computers and hardware first in the 1970s and 1980s and software a decade later). In the second place, unlike the late-industrialisation experiences of the East Asian Tigers, the subsumption of Ireland under the laws of motion of the NIDL did not start with the simplest organs of the collective labourer of large-scale industry. Instead, from the very beginning capital could profit in Ireland from the exploitation of the cheaper labour-power of medium-complexity productive attributes available in that national sphere of valorisation (alongside the requisite mass of unskilled workers it could also find there). These are the historical conditions that eventually came into fruition in the 1990s and which therefore underlay the impressive economic expansion associated with the Celtic Tiger boom.

At first sight, this phase of prosperity seemed to imply that Ireland had definitively overcome its historical condition as a reservoir of relative surplus population for the global accumulation process. However, the Celtic Tiger’s recent crisis seems to suggest that one should not rush to conclusions and that Ireland’s subsumption into the NIDL might not rest on very solid foundations. On the one hand, the very transformative tendencies of the material forms of production of relative surplus value that underlie the NIDL constantly make possible the integration of ever newer sources of even cheaper and more compliant but suitably-skilled labour-power. On the other hand, those very same tendencies revolutionise the means of communication and transport and thereby lead to the gradual erosion of any competitive advantage in geographical proximity to European markets that has also played its part in the peculiar forms taken by Ireland’s subsumption under the NIDL.

Notes

1. See the respective Chaps. 2 and 3 for an extended account of the determinations behind the incorporation of new territorial sources of raw materials for global capital accumulation and the consequent configuration of the 'classical' international division of labour.
2. See Chap. 2 and Starosta (2010) for the determination of small industrial capitals and their systematic release of surplus-value in circulation.
3. Surprisingly, Kirby (2010) quotes these figures as evidence of the 'initial success' of the new government's industrialisation policy.
4. Between 1932 and 1938 exports were also affected by the Economic War with Britain that followed the Irish government's decision to stop payment of land annuities owed to the British Exchequer and which had originated during the land reform period.
5. See Marx (1976: 794–802) on the different modes of existence of the relative surplus population resulting from the unfolding of the general law of capital accumulation.
6. See Chap. 4 for a further examination of these issues.
7. Although from an early stage the Irish working class lacked the relevant 'particularistic' technical skills, they possessed the 'universalistic' productive attributes (including flexibility and versatility) derived from a generally good level of basic education (Breathnach 2007: 136). As for the former particularistic productive attributes, note that most jobs in the newly emerging sectors initially were either 'unskilled' or, in a minority of cases, were 'semi-skilled' (Barry and Brunt 2002; Breathnach 1993); in both cases, those attributes could be more or less rapidly developed with 'on-the-job' training.
8. The government received £40.8 million plus a £6.5 million grant between 1949 and 1952, but total net capital inflow during those years amounted to £106 million (McAleese 1972).
9. Some authors place this low corporate tax regime on an equal footing with cheap but adequately-skilled labour power as the fundamental reason for the inflow of FDI into Ireland (Barry 2004: 16). O'Hearn (2003: 37) goes as far as considering it as essential to the inflow of FDI by TNCs, with an available pool of relatively low-waged IT experts reduced to a factor of secondary importance, since their wage bill is relatively low compared to other costs. These views fail to ask about the source of social wealth that can sustain such a low corporate tax without eroding the normal fiscal base of the capitalist state. In fact, O'Hearn unwittingly offers clues to this question. As he notes, the low corporate tax regime went hand in hand with a drastic and regressive rise in taxes on incomes and expenditures which, moreover, was not directed towards spending in basic social

programmes (O'Hearn 2003: 47–50). Thus, the levels of state spending on health, social housing, and education were among the lowest in Europe in the mid-1990s, with many social services run down. But this can only mean that the low corporate tax rate regime is only sustainable at the expense of undermining the normal conditions of long-term reproduction of the Irish working class—that is, at the expense of the purchase of labour-power at its full value. In other words, the low corporate tax regime seems to be but a concrete form of the exploitation of relatively cheap labour-power and not an independent factor in attracting FDI.

10. Concerning the IDA in particular, it is noteworthy that even those who see it as a planning agency that autonomously steered the form of integration into the NIDL recognise that in key cases the selection of (eventually successful) target industries usually follows a prior wave of uninvited inflows of FDI. Thus Barry (2004: 18) narrates that 'having attracted several computer and components firms in the 1970s, for example, and being favourably impressed by their performance in situ, electronics and computer software were among the industries listed as meeting these criteria in 1983, when an all-out campaign to develop Ireland as a major European location of such activities began'. Similarly, the turn to a deliberate 'export-oriented strategy' in Korea occurred *after* the *unexpected* impressive performance of exports towards the end of the 'inward-looking' First Five-Year Plan, which took even policy makers by surprise (Grinberg 2011).
11. Strictly speaking, as the experience of late industrialisation in Taiwan shows, it is possible for a mass of small capitals to turn into the active immediate subjects of the valorisation process on the basis of their subsumption under the NIDL. However this possibility must be predicated on a much cheaper labour-power and more brutal conditions of its consumption (that is, exploitation) than the historical conditions of reproduction of the working class prevailing in Ireland allowed. As for the Korean experience of generating national champions (that is, the *chaebols*), it must be noted that those large industrial conglomerates had already been created *before* the turn to 'export-oriented industrialisation' (Krause 1997: 138; Kim 1976; Woo 1991).
12. Although it is true that the share of exports to the UK tended to decline, it still reached 63.1 per cent in 1971. By contrast, the share of exports to the EEC reached only 12.4 per cent (other OECD countries took 13.8 per cent and all other areas 8.1 per cent) (McAleese and Martin 1972: 616–7). The composition of exports by destination was therefore very varied.
13. By 1980–1981 the occupational structure of the electronics industry in Ireland was, in international comparative terms of the complexity of labour-power, halfway between that prevailing in the USA and that in the, so-called, East Asian Tigers (Drew and Foster 1994; see also Barry and

Brunt 2002; Breathnach 1993). On the other hand, compared with the average Irish manufacturing occupational structure, the electronic industry is relatively more skilled.

14. PC assembly operations peaked in 1998 (when measured by employment figures) and started to shrink thereafter, so that by 2002 the only system assemblers remaining in Ireland were Dell and Apple (with the latter heavily downsized) (van Egeraat and Jacobson 2004: 813–14).
15. Evidence of this lies in the fact that, even allowing for a threefold overstatement of Irish figures due to transfer price fixing by TNCs to benefit from the country's low corporate tax policy, Ireland's software exports in 1990 were still seven times greater than those of Israel or India (Dossani and Kenney 2008: 56).

CHAPTER 7

New International Division of Labour and Differentiated Integration in Europe: The Case of Spain

Greig Charnock, Thomas F. Purcell,
and Ramon Ribera-Fumaz

The tendency toward a new international division of labour (NIDL) intensified with the crisis of general overproduction that engulfed the advanced capitalist countries in the 1970s. From the 1980s in those countries, trade union power was defeated, industries were privatised, labour markets were

segmented, and unemployment rates increased, while public spending on health and education diminished. The result has been a marked differentiation in the conditions of reproduction and exploitation of the working class *within* as well as across national borders—while, in general, average real wages have stagnated and income inequality has deepened. Iñigo Carrera (2013: 71–2; also Chap. 4) explains how this process unfolded in Europe through a form of differentiated integration:

> the gradual formation of a new national ambit of accumulation—and hence of a new national state—[is one] that starts by integrating formerly autonomous national spheres into a supranational organisation. The European Union includes national working classes bearing different histories with respect to their productive subjectivity and, therefore, with respect to the conditions in which they reproduce themselves. Under the concrete political form of an extended equality among their citizens, some countries of the union came to be suppliers of relatively cheap labour-power to the capital located in others. At the same time, the relative dissolution of each national unity allows an exacerbated regional and local differentiation in the internal reproduction of labour-power … Now, with an internal market that transcends [immediate national unity] capital maximises its accumulation on the basis of the regional and local differences in the reproduction of labour-power.

The more recent crisis of general overproduction that erupted with the collapse of large US investment banks in 2008, and which dragged much of the world's national economies into recession by 2009, has not only confirmed that a pattern of uneven development between countries exists in Europe, but also how crisis serves to further reinforce the process of internal differentiation of the reproduction of labour-power, particularly under the conditions imposed by European Monetary Union (EMU) and the adoption of a single currency, the euro.

While productivity increases surpassed wage growth in countries such as Germany between 1999 and 2007, wage growth and unit labour costs in the European South (including Ireland) outstripped the growth in labour productivity, which rose only sluggishly, stagnated, or (as in the cases of Italy and Spain) actually declined (Cambridge Econometrics 2011: 10; ILO 2013: 15–16). Economic growth and the expansion of social consumption across the European South during the 'boom' of the early- to mid-2000s rested instead upon the expansion of corporate and household debt, fuelled by an accelerated inflow and recycling of fictitious capital from the northern 'core' that was encouraged by low interest rates, banking deregulation, the high profitability of speculative urban and infrastructure construction and development (often linked to tourism), and the profitability of key non-tradable sectors in countries like Greece, Ireland, and Spain. A direct response to the 'Great Recession'—the sovereign debt problem arising out of banking bailouts and suchlike—across the EU has, as a consequence, consisted of the imposition of fiscal discipline and social austerity (Burnham 2011). Amidst rising unemployment and precarity across the Eurozone,[1] states have further sought to re-adjust national competitiveness by means of, so-called, internal devaluations (that is, reducing the cost of labour-power)—thereby deepening the structural differentiation of labour-markets within their respective national spheres.[2]

Much as Friedenthal and Starosta's contribution to this book asserts, it is of crucial importance that we understand the longer-term historical role played within the NIDL by relatively late industrialising countries if we are to grasp the essential relation between global transformations and (uneven) national development—and especially if we are to explain why and how some countries and regions are today bearing the brunt of crisis, austerity and internal devaluation in a unified Europe. As we will see in the case of Spain, it is precisely on the material basis of its full integration within the NIDL from the 1970s to provide a relatively cheap source of labour-power in geographical proximity to the European Economic Community's (EEC) market that the conditions of the reproduction of the working class were shaped, and it is this historical component that prefigured the process of differentiation within and across its borders since then—a process compounded and deepened by successive crises and the development of the NIDL itself since the 1970s.

The *Backward* Character of Capital Accumulation in Spain Prior to the New International Division of Labour

At first glance, there are perhaps reasonable grounds for comparison between the economic histories of Spain (and other southern European spheres of accumulation) and Latin American counties, since both have a history of late industrialisation on the basis of some version of a strategy of import substitution (ISI). In the Spanish case, after the fascist victory in the civil war (1936–1939), the national sphere of accumulation was largely closed to foreign imports of commodities as part of an especially restrictive, autarkist ISI policy.[3] Much as in Latin American countries at that time, the Spanish state imposed quantitative restrictions on imports, foreign exchange controls, a fixed and overvalued exchange rate, it controlled capital markets, and centralised the regulation of foreign trade—eventually administering it through a multiple exchange rate system. With such protectionist measures in place, the Franco regime created the Instituto Nacional de Industria (INI) in 1941; a state holding company charged with promoting national industrial development in key sectors—initially energy, iron, and steel production. Under ISI Spain began to industrialise, with average industrial growth rates in the 1950s four times higher than in the 1940s. By 1960, industry was contributing 30.93 per cent of GDP (Prados de la Escosura 2003: 584), with the INI having secured state monopoly control in over 60 national enterprises and across a range of sectors by the mid-1960s, including new sectors of national interest such as automotive manufacturing.

Yet there were always important differences between Spain—and other southern European countries that adopted ISI—and Latin America. One of the insights developed in the work of Iñigo Carrera (2007, 2013) concerns the specificity of the process of capital accumulation in countries where the relation between the total global social capital and the national sphere is politically mediated by ISI policies. This has historically been the case in ‘resource rich’ Latin American countries where the appropriation of ground-rent is mediated by state policies and institutions that transfer resources from the primary sector to the rest of the economy (see Chap. 3). The fundamental significance of national accumulation processes based upon the appropriation and recovery of ground-rent by the state, landlords, and (both national and global) industrial capitals is that the development of the forces of production proceeds on a limited, ‘backward’ basis, relative to world market norms. The appropriation of ground-rent compensates for higher production costs incurred by smaller, backward capitals, so they can nonetheless valorise at the general rate of profit. In Spain, however, given the absence of a sufficient magnitude of ground-rent and the limits inherent in the systemic payment of labour-power below its value (which was the primary basis for the valorisation of capital in the early years after the Civil War) ISI was always doomed to failure. The forms of compensation that extended the life of ISI up to the late 1960s were instead strongly dependent upon the expansion of capital accumulation outside Spain, and, as we shall see, in northern Europe in particular—which, of course, was drastically restricted in the general crisis of overproduction of the 1970s.

The primary basis for the valorisation of domestic capital in Spain prior to the 1960s was certainly the purchasing of labour-power below its value (Molinero and Ysás 2003; Vilar Rodríguez 2012: 7–8). While nominal wages increased slowly between 1939 and 1951, the rate of increase was maintained below that of wage-goods prices, resulting in the diminution of purchasing power for the majority of the population. In 1956, for example, the estimated real value of wages was between 15 and 35 per cent below the pre-Civil War level, with an associated low per capita consumption of staple foods (Lieberman 1982: 188). Nevertheless, by the end of the 1950s the limits to rapid industrialisation on the basis of an extremely restrictive version of ISI were beginning reveal themselves—and notwithstanding the additional compensatory benefits of bilateral aid agreements secured in this period (of note, the 1953 Pact of Madrid struck with the USA). By then, the state had exhausted its foreign exchange reserves, could no longer finance a spiralling budget deficit, and nor could it stave off workers' demands for wage increases in the context of high inflation.

The implementation of the 1959 Stabilisation Plan by Francoist technocrats—a turning point for most economic historians of this period—was a necessary response to a looming national crisis that expressed the limits to autarky. The Plan consisted of public austerity to attack domestic inflation coupled with the controlled liberalisation of imports. Multiple exchange rates were unified and, in Spain's joining of the Bretton Woods monetary system in 1961, the peseta was devalued and became convertible on international markets—thereby boosting the export capabilities of some national industries. Most significantly, however, new foreign investment regulations permitted up to 50 per cent ownership in Spanish firms, with no limits imposed on strategic sectors such as steel, textiles, shoes, leather, machine tools, and construction. As a result, between 1958 and 1972, Spain's most important local capitals expanded, but in turn (with the exception of the shipbuilding and electricity sectors) became heavily dependent upon FDI and foreign technologies in what constituted a later phase of the classical international division of labour (CIDL), in which foreign capitals invested in local capitals whose turnover cycles were largely opened and closed within the protected Spanish market.

The high levels of growth that Spain enjoyed in the 1960s were therefore based upon the continued reproduction of small industrial capitals (see Iñigo Carrera 2013: 136–8) producing for the domestic market. In the absence of a large magnitude of inter-sectoral transfers from primary materials exports that sustained ISI in Latin America, the Spanish state found that it could only sustain ISI beyond the 1950s due to three developments that brought into sharp relief the necessary relation between the national and the global (especially northern European) spheres of accumulation (Charnock et al. 2014: 48–50). First, the inflow of remittances from millions of Spaniards who left the country to work abroad (under different variations of the West German *Gastarbeiter* arrangement) had the effect of allowing Spanish households to consume wage-goods even when the state fixed wages below socially necessary levels (to the benefit of the valorisation of small industrial capitals). Second, flows of value from outside the national sphere of accumulation that arrived in the form of revenues from mass tourism had the combined effect of allowing Spanish workers employed (formally and informally) in the tourism economy to meet their subsistence needs, of expanding the domestic market, and, importantly, of allowing the Spanish state to finance its current account and balance of payments deficits. The third development was the arrival of restricted, incipient flows of FDI oriented toward production for the domestic market. In addition to the lowered costs of production provided by the exploitation of low-skilled, surplus labour-power in and from late industrialising countries, the rise in FDI from the 1960s can also be explained by the benefits that accrued from the importation of patents and machinery from abroad. States like Spain could establish a basis for the expansion of domestic industries by facilitating the import of technologies deemed obsolete by world market industry; that is, means of production that could no longer maintain the productivity of labour relative to new means of production and/or in new configurations of the labour process in specific branches of production for the world market, but which still served to raise the productivity of labour within the restricted scale of the protected domestic market, and so to raise the rate of profit for those small industrial capitals that put them to use in their labour process (the basis of, so-called, secondary ISI—see Phillips 2004: 43–4).

By 1974, however, Spain eventually did experience the onset of a global crisis of overproduction in the form of a crisis of ISI. The conditions were ripe, then, for Spain to assume a position within the emerging NIDL based upon the following conditions. First, that it offered foreign capitals the opportunity to relocate parts of the production process to a low-wage labour market,[4] and an economy in which internal demand was rising and obsolete industrial technology and patents could be profitably recycled by foreign industrial firms. Second, and after the state's watershed agreement with the Ford Motor Company (discussed below), which marked the beginning of a transition to the export-oriented subsumption of the national sphere of production to the NIDL, Spain offered foreign capitals geographical proximity to the expanding European internal market—a prospect that would be completed with the country's full accession to the European Community (EC) in 1986.

The Integration of Spanish Industry Within the New International Division of Labour: The Case of the Automotive Industry

From our perspective, an analysis of the Spanish automobile industry illuminates the basis upon which Spain was inserted into the NIDL from the 1960s, and allows us to examine the relation between global transformations and uneven national and regional development. Spanish automotive production was transformed in the 1940s under early ISI and the auspices of the INI, which established Sociedad Española de Automóviles de Turismo (SEAT) with a 51 per cent capital share in 1948 (the Italian firm Fiat providing the patents in return for a seven per cent initial share). In 1951, Fabricación de Automóviles SA (FASA) was created in Valladolid after an agreement was struck with the French producer Renault to produce FASA's vehicles under licence, with 70 per cent Spanish capital (mainly from Banco Santander), thereby establishing an effective duopoly in Spanish production (Catalan 2010: 211). By 1962, these firms were specialised in small vehicle production under Italian and French licences, and both fared well in the boom of the 1960s. By 1970, when the EEC reduced tariffs on Spanish imports, SEAT was Spain's leading export firm and its flagship 'national champion'. Yet, in García Ruiz's (2001) estimate, the development of the car industry was predominantly fed by rising internal demand up until 1967—the same year in which the state was forced to devalue the peseta in the face of a growing balance of payments deficit, the onset of rising inflation, and a brief recession that defined the limits of profitability on the basis of production solely for the domestic market (Román 1971: 86). Realising that the domestic market had reached the limits of its development, Fiat and Renault opted to permit exports of cars from Spain produced under their licence but demanded a greater share of SEAT and FASA, respectively, in return. However, the picture that had emerged by then was one of an industry that was technologically backward and increasingly dependent upon foreign investment and technology. Production by these firms during the 1960s and into the 1970s was characterised by small economies of scale, short production series, high labour intensity, technical backwardness, and the manufacture of products that were antiquated in relation to world market standards (García Ruiz 2001: 145; Ramos Barrado 1986). Outside the duopoly, the growth of an auxiliary components industry consisting of many small capitals was sustained largely by the state's insistence upon a 90 per cent quota of Spanish-made parts.

By the early 1970s, the limits to the ISI-based expansion of the Spanish car industry were being felt. Faced with increasing labour costs, SEAT's profits declined from a 4.2 per cent margin in 1967 to 2.2 per cent in 1971 (Catalan 2010: 216). At this time, the Ford Motor Company was also in negotiation with the Spanish state to invest USD 300 million in a new assembly plant in Almusafes, Valencia, in return for several concessions (Studer-Noguez 2002: 92–3). By 1972, in what are known as the Ford Decrees, the state agreed, among other things, to relax the quota on Spanish-made parts, to decrease tariffs on imports of Ford components, and to exclude imports from other foreign firms. For its part, Ford's aim was to assemble the small Fiesta car in Spain for the EEC market, taking explicit advantage of a flow of suitably qualified, guest-workers' labour-power now returning to Spain in the context of the European recession—'a welcome nucleus of already trained men' (Turner 1977: 41)—and saving on the cost of producing cars in the USA for export in short runs (Doz 1986: 72–3). Production of the Fiesta in Valencia commenced in 1976. The arrival of Ford therefore heralded the beginning of the transition toward a full insertion of the national process of accumulation into the emergent NIDL, based upon the export-oriented manufacturing of low-cost small vehicles of relatively lower technological complexity, and taking full advantage of the relatively cheap, adequately trained nucleus of labour-power then available to it.

The global crises of the 1970s impacted significantly upon the structure of the global car industry. Since then, production has been concentrated in a decreasing number of producers facing problems of over-capacity in European, Japanese and US markets—even in periods of growth. As the NIDL developed on the basis of transformations in the production process associated with *systemofacture*, and in the face of heightening global competition,[5] Spain became an attractive export base for Ford's global competitors, precisely on the basis of offering relatively low-wage labour capable of adapting to labour processes of relatively low complexity (Rubenstein 2001: 344). Following Ford, and the state's, relaxation of the Spanish-made components quota to 60 per cent for all producers in 1979, General Motors established a plant near Zaragoza to produce the Opel Corsa (launched in 1983). This, together with the effects of the crises of the 1970s, was disastrous for SEAT, whose market share in Spain fell from 51 per cent in 1973 to 26 per cent by 1980 (Catalan 2010: 222).[6] At the height of recession in 1981, Fiat relinquished ownership of SEAT back to the INI and negotiations commenced with the German producer Volkswagen that culminated in the transfer of 51 per cent of the company in 1986—marking the end of a period in which foreign capitals' presence in Spain was mainly on the basis of producing obsolete car models for the domestic market (Álvarez Gil and González de la Fe 1997).

From this moment, the position of the Spanish automotive industry became, in a sense, *intermediate*: its position within the NIDL was that of a producer and exporter of equipment and components of lower complexity, and an importer of higher value-added components (Catalan 2010: 222; Ramos Barrado 1986).[7] This position was further consolidated from the 1980s and into the twenty-first century as, confronted with rising production costs and falling demand, the global automotive industry's response to the crises of the 1970s was to seek to lower costs by adopting leaner production technologies and reducing the minimum efficient scale of production through the introduction of automated production technologies—mainly industrial robots and computer-aided manufacturing (see Grinberg 2013: 181–2). This transformation entailed the geographical dispersion of different moments of the production process and the expansion of networks of labour-intensive production of components by small-scale auxiliary suppliers. Unsurprisingly then, the takeover of Spanish automotive producers in the 1980s proceeded on the basis of the transformation of technologies and organisation of production in line with recent revolutions in the labour process (so-called Toyotisation, after the Japanese producer) (see Álvarez Gil and González de la Fe 1997; Pallarès Barberà 1997)—a process mediated by the then Socialist government's further relaxation of the legal restraints on foreign capitals' restructuring of the labour process and the quota of Spanish-made components.

Since the 1980s the structure of automotive production within Spain has become markedly differentiated, and in a manner consistent with the international fragmentation of the collective labourer in general under the NIDL—as explained below. From the 1980s there has been an expansion in the number of small capitals acting as auxiliary suppliers to foreign-owned capitals engaged in large-scale final assembly for export. The former produce products of low technological complexity, while the latter involve *relatively* more technologically complex, higher productivity labour processes (see Aláez Aller et al. 2009; Pallarès Barberà 1997, 1998; Truett and Truett 2001). In the latter's original equipment manufacturing (OEM) plants, capitals are compensated for paying higher wages due to relatively high levels of labour productivity; while wages in the auxiliary sector—in which a far lower proportion of workers are unionised—have been relatively low (Banyuls and Llorente 2010). The 2009 crisis and ensuing recession has further consolidated the Spanish automotive industry's position within the wider international and European division of labour—although it has also exposed it to further competitive pressures from the accession countries of central and eastern Europe, such as Hungary, where small cars and light commercial vehicles can be produced using relatively cheaper labour-power with sufficient capacity to work with relatively more complex technological processes than can be found in Spain (Minetur 2011: 42; also Aláez Aller et al. 2009: 51). Notwithstanding such pressures, Spanish automotive producers (who contributed 10 per cent of GDP and employed 9 per cent of the active labour force in 2013—PWC 2013: 39) increased output and direct employment since 2009, albeit on the basis of their lean, flexible reliance on components supplied by a mass of local small capitals (Anfac Research 2014; Galindo 2013). Indeed, the crisis has deepened the differentiation of capitals within the Spanish automotive industry, and to the extent that, firstly, producers have expanded their outsourcing practices in an increasing number of design, production, logistics, and assembly functions to auxiliary suppliers to reduce costs (Minetur 2011: 49).[8] Secondly, this process has accentuated the hierarchical relation between different tiers of components-supplying capitals within Spain: (1) those that belong to TNCs; (2) those small components manufacturers who have responded to competitive pressures by increasing their scale of production and upgrading technological processes; and, (3) those that have been unable to adapt to increased competition and whose reproduction is therefore at risk (Minetur 2011: 49–50)—further deepening the differentiation of the conditions of the reproduction of labour-power within the automotive industry.[9]

The New International Division of Labour and the Differentiation of Capitals and of the Conditions of the Reproduction of Labour-Power in Spain

The account above of the development of the Spanish automotive industry within the NIDL, reflects the general development of industry in Spain since the 1970s. To understand this development, it is crucial to bear in mind how state managers in Spain have struggled to create the necessary conditions for the expanded reproduction of capital since the crises of that decade and the political transition to a liberal democratic form of state. By 1977 the first civilian government in Spain had enacted a series of drastic economic policy measures, including curtailing the money supply, reforming labour legislation, and introducing wage controls. This occurred in the context of high interest rates across the classic capitalist countries, and the monetary squeeze that constituted part of a global disinflation strategy—the first move having been made by the US Federal Reserve and the, so-called, Volker shock of 1979. As is well documented in IPE literature, this marked an incipient process of economic and political restructuring that was ideologically justified by a new social realism and the championing of the free market (that is, neoliberalism). At the same time, the formal process of European regional integration gathered momentum. In this period, states across the European south had to find some way to confront the problems of falling profitability, high inflation, de-industrialisation, rising unemployment, and public deficits (Hopkin 2012: 38; Karamessini 2008: 514)—problems for which a single European market and monetary union were seen as the solution by successive governments.

Between 1977 and 1988 Spain's balance of payments steadily improved and inflation decreased (Boix 1995: 35), but at the cost of high numbers of closures of credit-dependent industrial firms and—under the Socialist government's industrial reconversion, or cleaning up programme (*el saneamiento*)—a total loss of some 700,000 manufacturing jobs (Lieberman 1995: 281–3). After the removal of restrictions on temporary contracts in 1984, fixed-term employment rose dramatically, reaching 30 per cent of total employment in Spain by 1991 (Jimeno and Toharia 1994: 18). From 1979 to 1986, real wages experienced a sustained decline (López and Rodríguez 2010: 148). Thus, the burden of transition toward a fully liberalised market and Spain's full insertion into the NIDL was placed squarely upon the Spanish working class (Etxezarreta 1991: 40). The rate of profit continued to rise throughout the 1980s up until the recession of 1992 (Nieto Ferrández 2007: 200). Meanwhile, according to Viñals et al. (1990: 161), labour costs in Spain by 1985 were about 43 per cent lower than in other industrialised countries, with the vast majority of new employment being on the basis of flexible contracts. At the same time, the growth of Spain's service sector and its recently territorially decentralised public sector—in the form of the 17 Autonomous Communities, which drew many women into employment in education, health and cultural sectors—began to grow disproportionately to manufacturing (Santos Preciado 1997: 155). From this point the markedly segmented character of the labour market (Vilar Rodríguez 2012: 21–2) served to reduce the membership base of the trade unions and to weaken their capacity to resist the downward pressures on wages and working conditions (Banyuls et al. 2009: 255; Boix 1995: 38).

Crucially, during this period levels of investment in industry remained relatively low; a problem exacerbated by a domestic banking crisis between 1977 and 1985 that restricted liquidity (and which culminated in the centralisation of 73 per cent of banking activity in the hands of the Big Seven large financial groups by 1984) (López and Rodríguez 2010: 154). Unemployment rose to 22 per cent by 1984, and was accompanied by the emergence of a huge informal economy as workers strove to cope with layoffs associated with the *saneamiento* (Benton 1992). The terms and conditions of work in industries such as textiles, footwear, toys, and other light manufacturing sectors were particularly affected by newly emergent subcontracting relations that transformed the spatial organisation of production in Spain and, with it, the structure of the Spanish labour market (see Santos Preciado 1997). The devaluations of capital and labour under industrial reconversion had, in short, provided a fresh supply of low-wage labour to Spain's small capitals and on the basis of flexible work contracts (90 per cent of all annual contracts issued from the mid-1980s, according to Martínez Lucio and Blyton 1995: 351), competing to supply to normal, foreign-owned capitals engaged in larger-scale production.

Since the 1990s Spanish industrial production has continued to be concentrated in a mass of small capitals whose development is either restricted to the scale required for local markets, or else is dependent upon their ability to survive in competitive, geographically-concentrated markets supplying mostly foreign-owned normal capitals with inputs of low- to intermediate-technological content (Cabrero Bravo and Tiana Álvarez 2012: 83; European Commission Staff 2015: 16). In terms of scale, for example, between 1990 and 1996 only 25.2 per cent of the 33,203 new manufacturing plants established in Spain had more than nine employees (Arauzo-Carod and Segarra-Blasco 2005: 150–1).[10] In sectors at the vanguard of the transformation of automation processes upon which the NIDL has been dependent (see Chap. 4), Spanish capitals have, in general, failed to develop in step with world market norms (Charnock et al. 2014: 70–2), notwithstanding the, so-called, multinationalisation of Spanish manufacturing firms from the 1980s (cf. Holman 1996).[11] The inflow of FDI in the 1980s did little to encourage investment in productivity by the majority of Spanish firms. Inter- and intra-industrial trade continued to be characterised by the export of goods of inferior quality to those being imported—a problem attributable to the pervasive use of relatively backward technologies (Martínez Zarzoso 1999). By 2005 Spain had invested just 1.03 per cent of GDP in R&D—half the average for the EU-15 (Mathieson 2007: 22).

The fifteen-year period following the 1992 recession in Spain nonetheless witnessed the aggressive expansion abroad of a select number of domestic banks and firms, to the degree that in 2005 the volume of outward FDI exceeded inward investment for the first time in Spain's history (Fernández 2011: 151). The bulk of Spanish direct investment abroad went into Latin America (see Santiso 2007). The basis for the expansion of some firms after the mid-1990s lay in the state's proactive role in the centralisation and concentration of capital in specific non-industrial sectors. The, so-called, big five (Endesa, Repsol, Telefónica, and the two major banks, BBVA and BSCH) were the main beneficiaries of state protection in the 1990s, and by 2004 shared more than 60 per cent of the net profits of the 35 companies that make up the Spanish stock market index (IBEX) (Etchemendy 2004: 648). By the mid-2000s, therefore, Spain's largest and most profitable capitals were concentrated not in general manufacturing sectors, but in sectors such as banking, construction, utilities, public services, retail, and hospitality. As we have explained, the relatively backward development of industrial capitals in Spain can be explained by their restricted production for the domestic market, on the one hand and on the other, on a scale required to compete in supply networks for foreign capitals (see Arocena 2004). Spain's most profitable capitals, on the other hand, reached the degree of concentration required to compete as normal capitals at the scale of the world market, and with the support of the state—albeit in specific sectors in which these capitals mainly opened and closed their valorisation processes abroad.[12]

One significant result of the outward internationalisation of certain Spanish capitals concerns the external debt that weighs heavily upon the state today. As the accumulation cycle intensified in Spain during the boom that ended in 2009, the state used growing tax receipts—especially from construction and housing—to support acquisitions abroad by Spanish firms under the terms of, so-called, goodwill payments (Chislett 2007: 4). Between 2005 and 2007, when the state boasted a current account surplus (generated from taxes collected during the height of the property boom), Spanish companies spent a total of €140 billion on domestic and overseas acquisitions (Royo 2009: 20–1). By the 2000s, therefore, Spain could boast globally competitive, internationalised capitals. Yet, at the same time, its domestic industries increasingly relied upon low-wage, low-productivity, informal labour-power producing either for local markets or in highly competitive and low-profit supplier networks. The uneven development of the branches of production in Spain was fed by large inflows of money capital that supported the internationalisation of select Spanish companies, unprecedented levels of growth in the Spanish construction sector,[13] and rising levels of debt-dependent private consumption.[14]

Crisis and the Compounded Deterioration and Differentiation of the Conditions of the Reproduction of Labour-Power in Spain

A national process of accumulation reproduced through the expanded consumption of imports over the production of exports, with stagnant or deteriorating productivity, but which grows at an annual average rate of 4.4 per cent for almost ten years, can only reproduce on the basis of some form of compensation, and, in the Spanish case, this was debt. The cycle of growth in Spain prior to 2008 rested upon huge inflows of fictitious capital from abroad (and especially from the European ‘core’ through the covered bonds market linked to mortgage-debt refinancing)—speculative investment that was switched into Spain through its savings and commercial banks into the then especially profitable construction sector and real estate market.[15] For much of the working class in Spain, expanded consumption during the pre-2008 boom depended upon rising levels of private debt and, often, upon cashing in the equity from rapidly rising house prices (López 2007: 219). The ratio of resident household debt to

GDP in Spain grew from under 55 per cent in 2000 to over 90 per cent in 2010,[16] while estimated net household debt as a percentage of disposable income grew from 85.97 per cent in 2000 to 144.32 per cent in 2006—almost 40 per cent greater than the eurozone average (OECD 2008: 25, Fig. 1.3).[17] As is widely acknowledged, the disproportionate expansion of the construction sector relative to other sectors during the boom raised the price of non-tradable goods and reduced the competitiveness of exports, fuelling inflation and exacerbating the need to fund social consumption through the further expansion of credit. Meanwhile, overproduction in the construction sector was endemic; between 2001 and 2011, there was a 24 per cent increase in housing stock (to more than 26 million homes), relative to just a 5.8 per cent increase in the population (to approximately 47 million inhabitants) (Stücklin 2013; see also García 2010).

In this context, it is not surprising that the dramatic rise in unemployment since 2008 has not been the only palpable indicator of the impact of the crisis on the working class (unemployment in Spain reached a record high in 2013 of over 6.2 million people, or more than 27 per cent of the population of working age, rising to 57 per cent for under-25s—INE 2014: 5). Indeed, the impact of the crisis on housing provision has been equally stark. Between 2008 and 2012 there were 172,000 court-ordered evictions in Spain as a result of mortgage payment defaults. By 2015 the rate of household evictions stood at 95 per day, in a country with an estimated 3.4 million empty homes (30 per cent of all vacant properties in Europe) (Keeley 2015). The sharp rise in unemployment has swelled the ranks of the surplus labour population in Spain, and to the extent that, by 2013, 12.6 million people were deemed to be at risk of poverty or social exclusion according to government figures (reported by European Commission Staff 2015: 6). The impact of the crisis from the point of view of capital is that internal devaluation (together with labour market reforms in 2010 and 2012) has borne fruit. Unit labour costs in Spain were reduced by 4.1 per cent between 2009 and 2013, while the cost competiveness gap between Spain and the core, northern eurozone countries narrowed due to wage moderation and some gains in productivity. Yet, the impact of the crisis on labour markets has been to fragment them further still; the share of temporary employment reached 24.6 per cent in 2014 (largely in low-wage, low-skilled positions), with 91.9 per cent of all new contracts in 2014 being fixed term (over half of which were for less than three months) (European Commission Staff 2015: 40). Meanwhile, Spain has once again become a country of net outward migration, as more and more workers leave to find work abroad.

The impact of the crisis upon the demand for labour-power in Spain in general has not been geographically uniform, however—a fact that reflects the differentiated development of industrial and non-industrial specialisation, and the uneven development of labour markets and the conditions of the reproduction of the working class within Europe and Spain. Of the ten EU regions with the highest unemployment rates in 2012, seven were Spanish (with six Spanish regions among the top ten EU regions in youth unemployment terms); while there were also four Spanish regions in the top ten EU regions in terms of increased unemployment rates, 2008–2012 (the others were in Greece) (European Commission 2013: 34, 36). In terms of the uneven impact of the crisis among Spanish regions, Andalucia, Aragon, Murcia, and Valencia saw their unemployment rate triple between 2007 and 2013 (Cuadrado-Roura and Maroto-Sánchez 2014: 8, 13), while the increase in jobless rates in other regions, such as the Basque Country, La Rioja, and Navarre, was relatively less pronounced—a situation that can largely be explained by longer-term, spatial patterns of regional specialisation in different productive sectors that saw the former regions concentrate production processes in construction and primary commodity sectors. The differences between the regions in terms of risk of social exclusion also reflects the uneven spatial differentiation in the conditions of the reproduction of the working class in Spain; while the rate of risk in the more industrialised, richer regions in the north—such as the Basque Country and Navarre—was less than 20 per cent in 2013, it ranged between 35 per cent and 39 per cent in the Canary Islands, Extremadura, Castille-La Mancha, and Andalusia—even reaching 47 per cent of the population in the city of Ceuta (Prats 2015).[18]

Conclusion

This chapter has offered an overview of the development of the Spanish national sphere of accumulation since the Civil War, tracing the material bases for this development within the CIDL as mediated by a—firstly restrictive and then relatively more open—ISI strategy on the part of the Francoist state. We argued that ISI was always beset by an inherently limited potentiality in Spain—the forms of compensation that extended the life of ISI therein being insufficient to sustain it beyond the late 1960s. Not only did the state's commitment to ISI put Spain on the path to a severe crisis by the mid-1970s, therefore, but it also prefigured the subsequent paths of both political transformation toward liberal democracy and the crisis-ridden integration into the European common market and, later, EMU. The failure of ISI to develop an industrial base of sufficient scale and competitiveness relative to world market industry meant that capital accumulation in Spain would continue to assume a specific, backward European form from the 1980s—even after consolidation of the process of subsumption of the national sphere of accumulation to the NIDL that began with the arrival of the Ford Motor Company in the mid-1970s and which unfolded through the, so-called, multinationalisation of the economy by the late 1990s. Ultimately, the Spanish case serves to illustrate a more general tendency toward differentiated, uneven integration in Europe in which the south is fast being 'reduced to a zone with a cheaper labour force, outside the safety network of the welfare state, a domain appropriate for outsourcing and tourism' (Žižek 2013)—a process based upon the fragmentation of the productive subjectivity of the working class and the on-going deepening of the internal differentiation of the conditions of the reproduction of labour-power, within and across various spatial scales within the Europe-wide sphere of accumulation.

NOTES

1. In 2013, the average overall employment rate in the EU stagnated at 64 per cent, with a declining rate among men; the EU-28 unemployment rate had increased to 11 per cent; and between 2008 and 2013 the overall pool of unemployed workers in the EU had grown by 10 million people. The proportion of long-term unemployed in the EU rose to 47 per cent in 2013. Nearly one in five EU workers then held a part-time job, with the proportion of available part-time to full-time work increasing markedly for lowest-skilled manual workers from 2008 (ETUI 2014: 43).
2. Fourteen EU countries have registered a decline in real wages since 2010—the largest reductions being in Greece (more than 23 per cent), Cyprus (−14 per cent), Romania (−13 per cent), Ireland (−6.8 per cent), Portugal (−6.5 per cent), and Spain (−6.1 per cent). Mediterranean and Central and Eastern European have also moved toward a more 'fragmented and decentralised model of collective bargaining' since 2009 (Schulten and Müller 2015: 350, 353; see also ETUI 2014: 68).
3. See Charnock et al. (2014: 40–4) for a review of the historical development of capital accumulation in Spain prior to the Civil War.
4. In 1979, Spanish wages in the automotive industry were 20 per cent less than in France, and 52 per cent less than in Germany (Pallarès-Barberà 1998: 350).

5. The number of producers in these markets has fallen from 36 in 1970, to 31 in the 1980s, 22 in the 1990s, and 14 by 2003 (Heneric et al. 2005: 34).
6. It is noteworthy that relations between the INI and the Italian investor Fiat became increasingly fractious from 1971, culminating in the latter withdrawing its stake in SEAT in 1981—the main issue being rapidly increasing labour costs as a result of concessions to the increasingly more militant trade union representing SEAT workers (Tappi 2007: 119–20).
7. Across Europe from the 1980s, there emerged a broader national and regional pattern of the uneven development of automotive production—a pattern into which the Spanish car industry's relatively backward position was further embedded. A spatial hierarchy in production emerged from the 1980s, with its productive and geographical centre in southern Germany (Bordenave and Lung 1996). There, and typified by Volkswagen, producers have since specialised in the production of larger, high-end, technologically advanced cars using the most complex labour processes, with the highest levels of labour productivity and concentration of R&D development and adoption (Rubenstein 2001: 343).
8. In some models, 80 per cent of components are supplied by sub-contractors (Minetur 2011: 49).
9. Including the differentiated capacities for different workforces to engage effectively in collective bargaining, depending upon the structural position of the capital employing them within the supply chain (see, for example, Las Heras 2015).
10. This remains a defining characteristic of local small capitals in Spain. By 2014, over 90 per cent of firms in Spain employed fewer than nine workers, and more than 50 per cent of workers were employed by firms with a workforces of less than 50 employees (compared with 23 per cent in Germany and 32 per cent in France) (European Commission Staff 2015: 18).
11. See Köhler and Woodward (1997) for a comparative study of the German and Spanish machine-tool industries; and the study of the Spanish steel industry by Montgomery and Sabaté (2010).
12. See Charnock et al. (2014: 77) for a discussion of Spain's other notable 'success story' since the 1990s—its fast fashion clothing production and retail industries, associated with brands such as Mango and Zara.
13. In 2007, construction accounted for 15.4 per cent of industrial output in Spain, compared with 4.7 per cent in Germany, 7.3 per cent in France, and 6.4 per cent in Italy (Cabrero Bravo and Tiana Álvarez 2012: 83).
14. The role of cheap credit in the internationalisation of some Spanish capitals was reflected in the rising level of corporate debt on the Spanish stock market in the mid-2000s; while private sector debt increased by 192.8 per cent between 1996 and 2010 to reach 227.2 per cent of GDP (Eurostat 2012).

The debt of non-financial corporations nearly doubled relative to GDP during the boom, from 74 per cent of GDP in 2000 to 137 per cent in 2008; by 2011, non-financial private sector debt reached 134 per cent of GDP, a rate second only to Ireland (Roxburgh et al. 2012: 27).

15. For an analysis of the material bases for overproduction in the Spanish real estate market, such as downward pressures on interest rates, land reform, the impact of the dot.com crash, the expansion of tourism and inward migration, and endemic *rentier* practices at the regional and municipal local state scales, see Charnock et al. (2014: Chap. 4).
16. International Monetary Fund data from 2011, at http://research.stlouisfed.org/fred2/series/HDTGPDESA163N (accessed 14 May 2013).
17. The ratio of household debt-to-income in Spain remained around 146 per cent at the close of 2014; while the total stock of private debt in Spain stood at 182 per cent of GDP—72.4 per cent of which was household debt, according to European Commission Staff (2015: 25, 29).
18. There are, of course, longstanding gender dimensions to the fragmentation of Spanish labour markets that have been exacerbated by the most recent crisis (Rodríguez Modroño 2014). For an analysis of the differential impact of the crisis on the disabled, migrants, the young, and the elderly, see Martinez-Molina et al. (2014).

PART III

Sectoral Case Studies

CHAPTER 8

Transnational Corporations and the ‘Restructuring’ of the Argentine Automotive Industry: Change or Continuity?

Alejandro Fitzsimons and Sebastián Guevara

Toward the end of the 1980s, the Argentine automotive industry had already experienced 15 years of stagnation and contraction following a peak of production in 1973. Nevertheless, a series of studies had begun to circulate that highlighted how its development might be revitalised following global production transformations (Jenkins 1985; Kosacoff et al. 1991; Todesca et al. 1989). In the 1990s, a new expansive phase of local automotive production prompted another series of studies that emphasised the transformations taking place during that decade (for example, Bisang et al. 1995), only for the limitations of such changes to be made

evident by the long crisis experienced by the Argentine process of capital accumulation between 1998 and 2002. But the strong expansion of the last decade has once again revived discussion about the 'restructuring' of the Argentine automotive industry (Barbero and Motta 2007; López 2007; Pinazo 2013; Santarcángelo and Perrone 2012). Beyond the differences due to theoretical approach and date of publication, it is clear that research on the automotive industry over the last 25 years shares a common point of view. In effect, most studies propose that restructuring has qualitatively changed the dynamics of the sector with respect to the preceding era. More precisely, the development of the local automotive industry is considered to have passed through two great 'models of development'. The first model, whose beginnings are located in the late 1950s and which ended at some point between the mid-1970s and late 1980s, is usually characterised by the orientation of production toward the domestic market, low levels of global productive integration, and limited international competitiveness. Owing to inward-oriented and relatively isolated production, this first stage of industrialisation is not seen as having been especially determined by the development of the international division of labour in this sector, but rather as part of the broader process of import substitution experienced by post-war Latin American economies. It is then usually argued that from the early 1990s the incorporation of the country into the new international division of labour (NIDL), through the reorientation of production toward external markets, put in place a second model of development. This new productive model permitted the overcoming—at least partially—of the shackles on growth deriving from the 'inward-looking' nature of the prior model.

A first aim of this chapter is to question this dominant account of the development of the Argentine automotive industry. In short, our argument seeks to highlight that the development of the NIDL in the global automotive industry did not result in a qualitative restructuring in the local automotive industry but, conversely, recreated it on the same bases as during the preceding period of the 1960s and 1970s. More precisely, we argue that even after the, so-called, restructuring of the sector, the valorisation of local subsidiaries of transnational corporations (TNCs) was based on the appropriation of a portion of ground-rent flowing into the Argentine space of capital accumulation as a result of its role in the classical international division of labour (CIDL) as an exporter of raw materials (see Chap. 3). In fact, we also argue that the development of the NIDL at global level did not appear 'from out of the blue' so as to qualitatively transform the Argentine automotive sector from a backward and isolated industry into a modern link in the international division of labour. Instead, we will see that technological change at global level, and changing forms in the international division of labour that derived from it, were fundamental determining factors from the very origin of the local automotive industry, and not only of its alleged modernisation through restructuring during the last quarter of a century. In this sense, a second aim of this chapter is to offer an analysis of the Argentine automotive industry based on the general approach developed in this book, which emphasises the persistence of the CIDL in the present day and its complementarity with the NIDL.

To tackle these objectives, we first concentrate on an analysis of the main arguments put forward by those who support the account of the qualitative restructuring of the local automotive industry, outlined above. Subsequently, we address a question that is almost universally avoided in specific studies of the sector, namely, the analysis of the concrete conditions of the valorisation of 'foreign', or TNC, capital in Argentina and, above all, its sources of profit. Finally, the last part of this chapter returns to the question of the historical long-term evolution of the Argentine automotive industry as part of the global automotive industry.

The, So-Called, Restructuring of the Argentine Automotive Industry

There is little doubt that the first stage in the development of the Argentine automotive industry—roughly from the mid-1950s to at least the mid-1970s—was characterised by its small scale, the use of backward technology by international standards, and the relatively low productivity of labour. In effect, the size of the domestic market proved insufficient for production under normal technological conditions prevailing in the most industrialised countries. For example, while production in Argentina reached a peak of almost 300,000 vehicles in 1973, annual output in the main European countries was between two to four million vehicles, that of Japan was more than five million, and that of the USA was some ten million vehicles. Due to the fragmentation of the domestic industry, in terms of both manufacturers and models produced, the technical difference in scale was even greater than that suggested by an international comparison of production levels. Even at its peak only a few models reached production levels of 15,000 annual units (Asociación de Fábricas de Automotores 1996). By contrast, according to various estimates from the period (see Husan 1997), the 'theoretical' minimum efficient scale of production was at least 200,000 units, while real production runs of the most produced models in the USA and Europe were greater still. In addition to the small scale of production, there also exists a consensus concerning the use of productive processes that were far from the cutting edge of technology at that moment (Baranson 1969: 46–8; Nofal 1989: 89–94; Sourrouille 1980: 121). In effect, Argentine factories were designed for productive processes with a high participation of manual labour. For example, in the machine shops production lines were initially planned with single stations, and manually controlled machines that allowed for the machining of many different parts. This meant that in each station the worker had to manually load, position, operate, and unload the machine and, in some cases, change the cutting tools for each sequence of the process (Nofal 1989: 90). Also, the transfer of the object from one station to another was done manually (Harari 2011: 143–4). In the press shop, moreover, the high rotation of dies imposed by the low volume of production (Baranson 1969: 47) made it impossible to automate the unloading of the presses, technology that was already in use in the USA by the 1950s (White 1971: 21). And, in final assembly the differences in scale mainly affected the speed of the assembly line, which was much slower in Argentina than in the USA. This resulted in a lower degree of worker specialisation and therefore of the machinery used; consequently, manual instruments were used instead of the automatic machines used in the USA (Baranson 1969: 47). In summary, while the global automotive industry was advancing toward the automation and deepening of large-scale industry through *machinofacturing*, factories in Argentina were predominantly organised around a manufacturing system based on the manual division of labour and not on a system of machinery.

Likewise, it is clear that the small scale of production had important negative consequences for the productivity of labour and the costs of local industry. In effect, productivity throughout the 1960s was between two and three times lower than in Europe, and more than five times lower than in the USA (Asociación de Fábricas de Automotores 1969). The low productivity of the sector, and subsequently of the auto-parts industry, appeared to have strong repercussions for costs of production which, it has been estimated, were twice those of the USA in 1967 (Baranson 1969: 34).

For these reasons, the majority of researchers have been very critical of this first stage in the development of the Argentine automotive industry. Their criticism has been directed toward state policies, which are deemed to have been misconceived or poorly implemented (Remes Lenicov 1973); or, alternatively, toward TNCs for their oligopolistic, speculative, and/or absenteeist strategies (respectively Sourrouille 1980; Schvarzer 1993; Nofal 1989). These motives, it is argued, prevented the domestic automotive industry from reaching normal international standards of productivity and quality. This argument presupposes the idea—sometimes explicitly—that the Argentine automotive industry could (and should) have superseded a first, 'protected', stage in order to reach a second, 'competitive', stage. The failure of this transition would, for such researchers, ultimately explain the 15 years of stagnation and contraction in the industry from the mid-1970s as being due to a fall in domestic demand and the trade policy implemented by the state.

Nevertheless, and albeit after a prolonged delay, the Argentine automotive industry resumed its growth from the early 1990s, surpassing the 1973 level of production by 1994. The number of firms operating in the country, which had fallen during the 1980s, rose again with the re-entry of various TNCs that had withdrawn in the heat of the crisis, and with new entrants. As mentioned in the introduction, the argument that emphasised profound changes in the dynamics of the industry gained credence among scholars thereafter. Furthermore, the strong recovery of the industry after the crisis of 2001, which raised domestic production to levels that far exceeded pre-crisis levels, only appeared to vindicate the restructuring thesis. In effect, various recent studies argue that the Argentine automotive industry has left behind its inward-oriented character, so as to integrate itself in global value chains. From this perspective, this was possible because of the growth in the scale of production, the modernisation of factories, the multiplication of labour productivity, and the fall in real wages, which jointly contributed to increasing competitiveness by means of reducing costs. As a further consequence, it is underlined that foreign trade by the sector has noticeably increased (Barbero and Motta 2007; López 2007; Pinazo 2013; Santarcángelo and Perrone 2012).

The principal problem of these studies is that they tend to restrict their analysis to the domestic sphere, leaving international comparisons in the background. That is, they affirm the positive changes in national indicators with respect to their previous performance but without sufficiently taking into account that the industry was also 'restructured' at a global level.

Even if they do explain the domestic transformation by departing from global transformations, they overlook that the latter were much more profound than the former, such that all improvements within national parameters are dwarfed when compared internationally. As we show, this demonstrates once more the permanence and, indeed, the deepening of the long-standing gap between national and global production conditions.

To begin with, although it is true that the absolute growth in production was significant, especially in recent years, the domestic scale of production continued to lag considerably behind that of the rest of the world. Even in 2011, a record year for domestic production, output in Argentina only reached one per cent of world production (a level only marginally superior to the 0.76 per cent achieved in 1973). On the other hand, although the relative gap in scale was reduced with respect to the 'classic' producing countries in the automotive industry, the difference in 2011 remained significant: in that year Argentine production was 9.5 per cent of that in the USA; 13 per cent of that in Germany; and 9.9 per cent of that in Japan (the absolute gap in scale, of course, greatly increased). Further, in relation to emerging economies the evolution was markedly negative. While in 1973 between two and three times more vehicles were produced in Argentina than in South Korea and India, in 2011 production in both of those countries was five times that of Argentina. Even with respect to Brazil the relative size of domestic production decreased, going from 39 per cent to 24 per cent between 1973 and 2011. And further still, if we include China, the difference in scale between Argentina and the currently largest global producer remains at the same level as in the 1970s, that is, around a difference of twenty times in the level of production.[1]

The persistence of high levels of fragmentation in the domestic industry, in contrast with a strong global tendency toward the centralisation of capital, tended to counteract any improvement that could have resulted from the increase in absolute scale at the national level. While during the contraction of the 1980s the number of firms in the automobile manufacturing sector had been reduced to three, the subsequent expansive phase was accompanied by an increase in the number of automotive firms, such that there are currently eight firms in the same sector. As a consequence, differences in scale by firm and by plant were greater than the aforementioned gap in national scales. Additionally, in spite of the specialisation derived from regional integration, the proliferation of models also maintained a characteristic limit to economies of scale in Argentina (see Tables 8.1 and 8.2).

Table 8.1 Largest automotive producer by country, 2013

Country	*Firm*	*Units produced (thousands)*
Japan	Toyota	4290

As a consequence of the persistence of problems of scale, the modernisation of domestic plants was also limited in extent. During the 1990s, when the importation of machinery was made much cheaper by the strong overvaluation of the national currency (see Chap. 3) and facilitated by trade liberalisation, modernisation consisted fundamentally in the relative flexibilisation of the pre-existing electro-mechanic technical base, and not in its replacement with microelectronics. For example, a study of the changes implemented in the Ford factory shows that, instead of renewing machinery, old presses in the stamping section (in production since the 1980s) were adapted through the attachment of numerical control units. In a similar way, the introduction of robots was limited to specific tasks in certain sections (especially in welding), co-existing with traditional manual labour in other operations (Lascano et al. 1999). In fact, the largest innovations were applied to new forms of work organisation (especially team-work) rather than to technical change; and even in this case the application was partial and by 'hybridising' methods used in parent companies with those being applied locally (Motta et al. 2007: 256). Therefore, by applying certain microelectronic components into old electromechanical machinery, and partially reorganising labour relations, capital could increase labour productivity without needing to comprehensively renew the equipment being used. As a result, the level of automation in Argentina, although higher than in previous decades, remained substantially lower than in Japan or the USA (Motta et al. 2007: 264). And the same could be said about the implementation of robotisation (López 2007: 43).

With regard to labour productivity, international comparison also brings into question the restructuring thesis based upon an analysis restricted to the national sphere. For instance, even at the peak of production in the years 2011–2013, output per worker was still two and a half times lower than in the most industrialised countries, and the productivity gap in absolute terms was more than twice that of the 1960s (see Table 8.3).[2] Moreover, if we consider the labour productivity of the best performing factories in different countries instead of national averages, the productivity gap increases notably (see Table 8.4).

A final argument put forward by defenders of the restructuring thesis rests on the increase in foreign trade. From this perspective, this rise demonstrates the definitive abandonment of the inward-looking model. Effectively, Argentina came to export, on average, 50 per cent of production between 1995 and 2013, with peaks of more than 60 per cent. This situation makes the development of the Argentine automotive industry resemble that of other 'emerging' countries that were fully incorporated within the NIDL, such as Spain, South Korea, or Mexico. However, to fixate on this indicator can be misleading. To begin with, exports as a proportion of total production in these latter countries is significantly higher, oscillating between 70 per cent and 80 per cent. Of more importance are the differences between the markets to which these other countries export and the destination market for almost all Argentine exports, that is the Mercosur (the common market of the Southern Cone).[3] The latter is much smaller in comparison to other regional and even national markets, being half that of the Japanese domestic market, almost a quarter of the European, and more than five times smaller than the US market. Furthermore, it is highly protected, as is shown by the continued dependency of Argentine industry on the Mercosur's limitations on foreign competition.[4] But, above all, the principal restriction on the Argentine external market is due to the limited character of regional integration. In effect, far from being a complete integration of national markets within a larger regional market, the regime of automobile foreign trade between Argentina and Brazil was structured around rules of compensated exchange. As a consequence, access to the protected Brazilian market is conditional upon the proportional opening of the domestic market to imports from Brazil. Therefore exports, and as a consequence domestic production, remain limited by the size of the internal market, however much regional integration has permitted an increase in the specialisation of each country in terms of models produced.

In summary, international comparison allows us to conclude that the majority of characteristics usually deemed specific to the Argentine automotive industry in the 1960s and 1970s are, in fact, reproduced today, namely: production restricted by the size of the domestic market; a substantially smaller scale of production than in the principal producing countries; technology that is way behind the frontier of technical innovation; and, finally, relatively low labour productivity. Yet, alongside these limitations, another important characteristic is also reproduced, that is, the operation in the country of the principal automotive TNCs. And, furthermore, it is the case that the TNCs in Argentina have consistently obtained rates of profit equal to, or even higher than, those existing in the sector at global level, at least during the expansive stages of the industry (Sourrouille 1980; Fitzsimons 2014; Pinazo 2013). This begs a question that has not received the attention it deserves, despite it being crucial for an understanding of the development of the automotive industry at the domestic level, namely, how do TNCs manage to obtain normal (and sometimes extraordinary) rates of profit with small scales, backward technology, and generally obsolete systems of production?

Specific Sources of Profit for Automotive TNCs in Argentina

In order to reemphasise its importance, let us reformulate the problem. The normal source of profit for any industrial capital is the surplus labour of the workers it employs. However, the achievement of a normal rate of profit is conditional upon those workers producing under the normal technical conditions for the sector. Otherwise, the lower relative productivity of labour would result in a smaller quantity of physical production per unit of labour-time and, therefore, in greater 'individual values' of the commodities produced (Marx 1976: Chap. 12); or, more precisely, in greater individual prices of production relative to those that correspond to average social conditions. But, given that the social determination of value (price of production) depends precisely upon these average or normal conditions, the greater values or individual prices of production are not recognised in the market. In other words, backward capitals waste (surplus) labour-time by producing under suboptimal technical conditions, which results in their immediate incapacity to valorise normally due to their higher costs of production. Consequently, those capitals that operate in technical conditions inferior to normal capitals can only obtain normal profits if they regularly access other compensatory sources of profit, sources that are distinct from the appropriation of normal surplus-labour carried out by their own workers. In this sense, we argue that automotive TNCs in Argentina compensate for the relatively low productivity with which they operate, and for its corresponding effect on costs, on the basis of the existence and possibility of appropriation of extraordinary sources of profit.[5] What, therefore, were the extraordinary sources of profit in the Argentine automotive industry?

It is immediately obvious that greater costs of production can be compensated for either by selling at prices superior to those of socially existing prices of production, or by the payment of below normal wages.[6] Indeed, the two main existing responses in the literature to the problem we have posed (even if this problem is not clearly formulated in those studies) revolve around these two situations. On the one hand, the most widespread position has focused on the oligopolistic and/or speculative behaviour of TNCs, which would have allowed them—together with state policies—to focus their valorisation strategy on the imposition of abnormally high prices, instead of technical innovation, thereby perpetuating the inefficiency of the sector (Jenkins 1984; Nofal 1989; Schvarzer 1993; Sourrouille 1980). On the other hand, more radical approaches—and in particular those related to dependency theory—have placed greater emphasis on low domestic wages in relation to those in the more industrialised countries, which they immediately interpreted as a form of the 'super-exploitation' of the domestic working class (Cimillo et al. 1973; Marini 2007). We think, however, that both analyses have focused only on the superficial manifestations of the valorisation of TNCs, and have failed to identify the precise sources of social wealth which the latter appropriate via high prices and low wages.

Let us begin with the question of prices. The vast majority of scholars tend to agree that during the, so-called, inward-looking stage internal prices were set above international prices as a result of the prohibition on imports of finished vehicles (Jenkins 1984: 46; Sourrouille 1980: 81). Although barriers to imports were lifted after 1975, other restrictions replaced them, such as quota systems, compensated exchange, and tariffs. The difference between international and domestic prices was therefore maintained, allowing for the continuity of local sales of both domestically produced and imported vehicles at high prices, as has been repeatedly shown in the specialised literature (CENDA 2008; Guevara 2010; Llach et al. 1997; López 2007). But it is often overlooked that this means that, throughout the history of the Argentine automotive industry, there has been sufficient solvent demand to validate domestic prices that were consistently set above global prices of production. As a result, one must explain the sources of this exceptional purchasing power on the part of Argentine consumers relative to those of other countries.

A first explanation may be found in the market destination of automotive production. It is the case that in Argentina there is demand for vehicles for use as means of production and/or for the transport of agricultural commodities. The greater costs that agrarian capital must incur in paying for its automotive means of production above its price of production can be transferred upwards toward the rent of the landowning class. Consequently, the social wealth that flows to TNCs via the sale of their product at commercial prices superior to those of production is, in the corresponding proportion, a part of the agrarian ground-rent whose appropriation determines the specificity of capital accumulation in Argentina (see Chap. 3). In this sense, it is worth noting that, in the period 1960–1975, the Argentine automotive industry was especially oriented to the production of commercial vehicles (see Table 8.5). Although the proportion of commercial vehicles to total output later fell, the specialisation in the production of commercial vehicles grew considerably in the period of expansion after the crisis of 2001 (see Table 8.6). On the other hand, although it is difficult to estimate its importance quantitatively, another portion of production was certainly destined for the personal consumption of landowners. As is evident, the source of this purchasing power is also ground-rent. The existence of a sumptuary component in the consumption of vehicles in Argentina is obviously consistent with the relative importance of large cars in domestic automobile production in comparison with Europe and, further still, with Japan, especially in the 1960s and 1970s, when mainly small and medium vehicles were consumed in those countries (Table 8.7). In summary, both characteristics of the 'product mix' of the Argentine automotive industry appear to indicate that an important portion of the vehicles produced is linked to the cycle of agrarian capital, or with landowners' consumption, and that therefore overpricing acts as a vehicle for the appropriation of ground-rent on the part of TNCs.

Agrarian ground-rent also generated growing demand for automotive vehicles in general (and not only for those directly consumed by agrarian

capital and landowners). It did so because one of the normal courses followed by agrarian ground-rent in Argentina has been its primary appropriation by the national state and its subsequent conversion into public spending.[7] In this way, agrarian rent augmented the demand for industrial commodities in general, including that of the automotive industry. Consequently, the overpricing of vehicles destined for general domestic consumption was also sustained, at least partially, by agrarian ground-rent.

In summary, the existence of ground-rent was, directly or with the mediation of state policies, a source of growing demand for automotive vehicles. This explains the setting of domestic sale prices above international prices of production. Without this extraordinary source of social wealth that validated those relatively high prices, the fixing of protectionist measures—at national or regional levels—would simply have contracted the consumption of vehicles, instead of expanding it, as happened in Argentina, in every one of the growth phases of the industry.

As we saw, the second main response offered to the question of the sources of valorisation of automotive capital in Argentina is linked to the payment of low wages, in international terms. Usually, any ‘advantage’ derived from the hiring of cheap labour-power is interpreted simply as a reduction in costs (Barbero and Motta 2007; Jenkins 1985; Santarcángelo and Perrone 2012), without identifying the reasons for existing wage levels nor the source of the advantage in question. Dependency theory, for its part, simply asserts that this amounts to the ‘over-exploitation’ of labour-power; that is, the source of profit in the ‘periphery’ lies in the greater degree of extraction of the surplus labour from workers than in ‘core’ countries (Cimillo et al. 1973: 55–6, 95–7; Marini 2007: 124–31). We think, however, that the question of the conditions of the hiring and exploitation of labour-power deserves a deeper analysis.

To uncover the source of the advantage obtained by TNCs through cheapened purchase of labour power, it is crucial to transcend the simple comparison of wages by means of existing official exchange rates, as is usually the case in the aforementioned studies. In Argentina the official valuation of the currency (through diverse instruments of economic policy) has been a recurring form of the appropriation of social wealth. This distorts any effective comparison based on this variable. It is clearly necessary, therefore, to correct deviations in the official exchange rate with respect to the parity corresponding to the real capacity of the national currency to represent value. This allows us to capture more adequately the magnitude of value represented in the monetary wage received by Argentine automotive workers in relation to other countries. Taking the method of relative purchasing power parity over a base period (Iñigo Carrera 2007: 31–3),[8] it can be concluded that, in terms of value, the Argentine automotive wage has historically been between three and four times lower than its US counterpart (see Fig. 8.1). This means that, in order to put an automotive worker into production, TNCs must disburse as much as three to four times less variable capital than if they had to hire labour-power in the socially normal conditions of exploitation of labour-power prevailing at the global level.[9]

Nevertheless, this cheapening of labour-power does not necessarily imply a greater exploitation of labour-power. Leaving aside questions relating to the extension of the working day and the intensity of work,[10] the comparison of real wages shows that the Argentine automotive worker was capable of consuming between one half to three quarters of the levels of consumption reached by a US worker (see Fig. 8.1).[11] This means

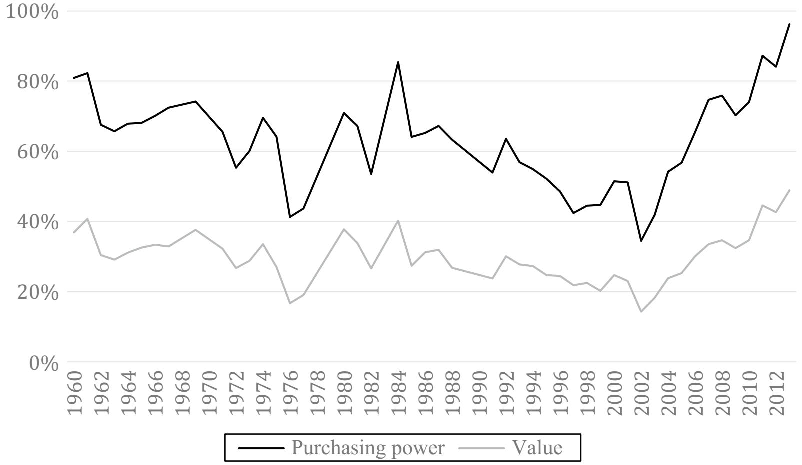

Fig. 8.1 The automotive wage in Argentina as percentage of the US wage. *Sources*: see Appendix

that the Argentine worker's ability to consume was much closer to that of the American's than is indicated by the value of her or his wage; or, put another way, that the Argentine worker could purchase more use values per unit of value than their American counterpart. The explanation for this situation resides in the domestic prices of wage goods for the working class. In effect, within the Argentine space of capital accumulation agrarian commodities circulate more cheaply than in the world market. Given that the domestic sale of these commodities below their normal price of production is only possible because of the existence of agrarian ground-rent, the cheapening of labour-power constitutes a vehicle for the appropriation of this rent by industrial capital and, in our case, by automotive capital. In brief, the process of appropriation of ground-rent by industrial capital explains, to a large extent, the relative cheapness of labour-power in Argentina. Quantitatively, this determination explains half of the difference between the Argentine and American automotive wage in the period 1960–2013. We see in the next section that, especially in periods of a relative contraction of ground-rent, this relative cheapening of labour-power has been complemented by a direct fall in real wages. In other words, what is at stake is not only the cheapening of the means of subsistence but also a fall in consumption on the part of the working class.

In conclusion, the preceding analysis shows that the fundamental basis for the valorisation of TNCs in Argentina has been the appropriation of a portion of the agrarian ground-rent circulating in the country, both through the purchase of cheapened labour-power and through selling at prices that have been set above those of production.[12] In this way, automotive TNCs have compensated for the backward technical conditions in which they operated. However, to do so they have had to complete their cycle of valorisation within the national (or regional) market. This is for two reasons: first, because the maintenance of those higher sale prices required tariff protection; and second, because the extraordinary profit gained from the cheapening of labour-power would have been more than offset had they oriented production toward exports. In effect, we have seen that a tendency to overvalue the currency has been a defining trait of the Argentine process of capital accumulation, precisely because of its role as one of the most powerful mechanisms for the appropriation of ground-rent.

However, while this specific form of the valorisation of capital explains to a large extent the main characteristics of the development of the automotive industry in Argentina (that is, the presence of the main TNCs, the orientation toward the domestic market, backward technology, and so on), we must also explain its historical evolution. In particular, the diverse phases through which the industry has passed at the domestic level, and the transformations involved, even though the most fundamental form of valorisation has remained essentially unchanged.

Change and Continuity in the Argentine Automobile Industry

A first challenge is to explain the precise moment of the establishment of TNCs in the country, which took place toward the end of the 1950s. The mere possibility of appropriating agrarian ground-rent is obviously not sufficient, since this possibility was present in its general form long before then. From our point of view, to be able to answer this question it is crucial to focus on the global development of the post-war automotive industry, so as to identify the determinations of the international expansion of TNCs in those years.

It is worth pointing out that the automotive branch of production was one of the pioneers, toward the mid-twentieth century, of the development of the automation of the productive process of capitalist large-scale industry. Before then, its system of production was based on a combination of the manufacturing division of labour and the mechanised assembly line (Grinberg 2011: 133–4; Coriat 1982: 27–43). The introduction of transfer machinery and, above all, its mechanical connection in an automated production line (a system known as fixed automation), triggered a spatial reorganisation of the global automotive industry. In enabling the incorporation of less-skilled labour-power as an appendage to the system of machinery, technical changes boosted the automotive industrialisation of East Asia; first in Japan, later in Korea, and later still in other countries of the region. In fact, the link between the development of automation and the emergence of East Asia as a region of industrial production for the world market has been at the core of the classic NIDL thesis. But the link between this technical revolution and Latin American industrialisation—including, of course, Argentina—has been frequently overlooked in the literature. We think that this point is key to understanding the process in the latter.

To begin with, the technical revolution took the concrete form, as always happens in the capitalist mode of production, of the intensification of competition between individual capitals for the appropriation of surplus profits related precisely to the innovation process (Marx 1976: 433–6; 1981: 279, 300–1). In turn, this competition imposed the need to discard increasingly obsolete machinery by virtue of what Marx called 'moral depreciation' (Marx 1976: 528; 1992: 250, 264), even if this machinery remained useful in the technical sense. This general determination was intensified in the case of US firms, which were widely dominant in the world market up to that point, due to the fact that automation had made possible the accelerated development of capital accumulation by European and, especially, Japanese firms (Pratten and Silberston 1967: 81). In effect, the relative cheapness of the labour-power in these latter regions made them more adequate for the incorporation of the new technical base, which required less-skilled labour-power. US firms, in contrast, were facing a double obstacle to technical change. On the one hand, labour-power was relatively expensive, owing to its higher qualifications (Grinberg 2011: 136–8); on the other hand, they were stuck with a large magnitude of fixed capital, corresponding to the antiquated technical manufacturing base, whose material form was increasingly obsolete (Wilkins and Hill 2011: 408). In summary, this was a period in which the automotive TNCs, especially US firms, faced a strong need to discard machinery so as to accelerate technical change in their home countries.

It was, in fact, this antiquated capital, obsolete for the new normal technical conditions, which was relocated to Argentina.[13] US firms principally [which were responsible for 60 per cent of foreign direct investment (FDI) in Argentina], but also European firms, found in Argentina a highly profitable alternative to the scrapping of obsolete machinery. In fact, the initial FDI in the Argentine automotive industry was directly made to a large extent in the form of machinery, equipment, and dies, with little or no investment in the form of money-capital (Sourrouille 1980). Also, there exists abundant evidence, as much qualitative as quantitative, attesting to the second-hand character of a good part of this machinery.[14] It is therefore especially significant that the sectors with the greater proportion of antiquated equipment were the machining, painting, and stamping sections (Asociación de Fábricas de Automotores 1969)—the very phases of the labour process in which automation had made more progress at the global level.

This antiquated machinery, already obsolete for the level of technical development prevailing at the global level, could be put into production in Argentina as a result of the specific form of valorisation centred on the appropriation of ground-rent. On this basis, the automotive TNCs increased their production in the country between 1960 and 1974. However, this 'strategy' had a very definite limit. In effect, the reproduction of this form of valorisation depended upon a sufficient quantity of ground-rent as a source of compensation for the lower productivity of labour. In other words, the reproduction of capital accumulation in the automotive industry was dependent upon the TNCs being able to access agrarian rent so as to obtain the normal rate of profit. But it so happened that the quantitative necessity for ground-rent as a source of compensation was growing, since technical change continued at global level. From the mid-1970s in particular, the development of microelectronics tended to widen the productivity gap between normal conditions of production at global level and those prevailing in the Argentine process of accumulation.[15] For its part, after the strongly cyclical movements of the 1970s, ground-rent stagnated in the 1980s at levels similar to the 1960s (see Fig. 8.2). Following a similar movement to the process of capital accumulation as a whole in Argentina, the combination of a growing necessity for sources of compensation and the stagnation of ground-rent brought the local automotive industry to a period of crisis and contraction between the end of the 1970s and the beginning of the 1990s.

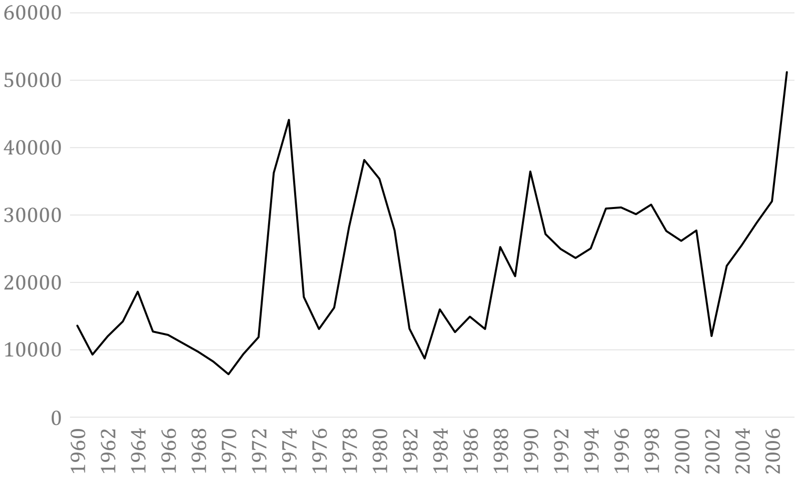

Fig. 8.2 Total agrarian ground rent (millions of 2004 ARS). *Source*: selected data from Iñigo Carrera (2008)

Various determinations combine to explain the recovery of the Argentine automotive industry during the last 25 years. First, the availability of agrarian ground-rent recovered from the contraction of the 1980s and stabilised in the 1990s at levels superior to those reached previously (with the exception of the relatively isolated peaks of 1974 and 1979; see Fig. 8.2). This increased source of extraordinary profit was appropriated by TNCs through the already analysed mechanisms linked to high domestic prices and the cheapened purchase of labour-power, to which could be added, in the latter decade, the remission of profits abroad with a sustained overvaluation of the currency.

However, and second, the conditions of purchase and exploitation of labour-power had worsened sharply as an expression of the general crisis in the national sphere of capital accumulation from the mid-1970s. In effect, the consumptive capacity of the automotive wage fell strongly from 1995, reaching levels in 2003 that were comparable with the most repressive years of the last military dictatorship (1976–1978).[16] In a comparative perspective with the USA, the wage fall in Argentina was of a greater size; in 1996–2003, the consumptive capacity of the Argentine automotive worker was 45 per cent that of the US worker, in contrast to almost

70 per cent in 1984–1988 (see Figs. 8.1 and 8.3, and Appendix). This divergence in the conditions of reproduction of the working class does not seem to derive from differences in productive attributes demanded from automotive workers in each country. If anything, the lower degree of automation of production in Argentina compared with the USA, and therefore the lower degradation of the productive attributes of the worker in the former country, would indicate an inverse relation to that which actually developed. Therefore, this absolute and relative fall in the Argentine real wage shows that the wage was, at least in this period, clearly lower than the value of labour-power. In this way, a second explanation for the recovery of the automotive industry is based on the emergence of a new source of extraordinary profit, namely, the appropriation of a portion of the value of labour-power. This fall in the level of the consumption of the working class adds to the cheapening of agrarian commodities seen earlier, increasing further still the wage difference (in terms of value) between Argentina and the USA.

Certainly, the pronounced recovery of the automotive real wage from 2004 tended to erode this new source of profit for automotive capital. But, simultaneously, the agrarian ground-rent grew abruptly, reaching levels much higher than those of the 1990s.[17] In this way, ground-rent

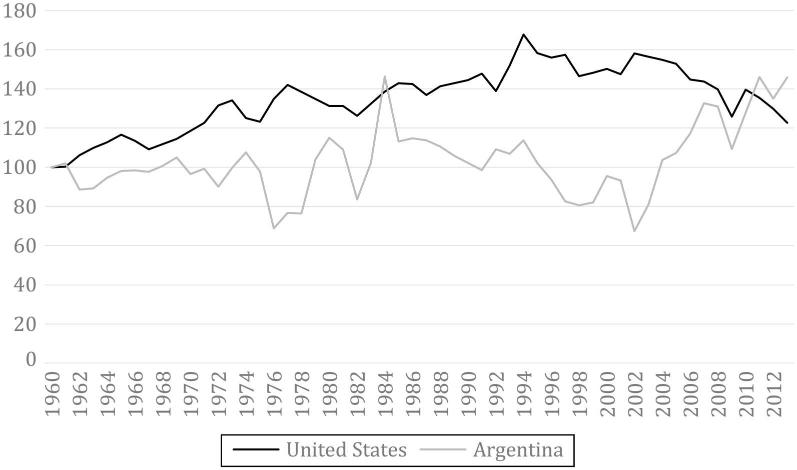

Fig. 8.3 The real automotive wage in Argentina and US (1960 = 100). *Sources*: see Appendix

resumed its leading role as a source of extraordinary profit for automotive capital, displacing the centrality of the sale of labour-power below its value. In effect, at least according to the data offered by the automotive firms, the recovery of the real wage in the years of the greatest boom in the sector (2011–2013), brought the consumptive capacity of Argentine workers to levels close to those of US workers. Despite this virtual equalisation in consumption levels, the relation between Argentine and American wages was 45 per cent in terms of value, demonstrating the full validity of the appropriation of ground-rent via the cheapening of the consumption bundle of labour-power in Argentina. Another element that demonstrates the renewed importance of ground-rent in the valorisation of automotive capital is the resurgence of specialisation in the production of commercial vehicles destined for use in the production and circulation of agrarian commodities (see Table 8.6).

The above perspective on the evolution of the forms of valorisation of automotive capital in Argentina allows us to put forward a novel point of view on the content of the, so-called, restructuring of the local automotive industry. In effect, far from implying qualitative changes in the functioning of the sector, the changes that took place over the last 25 years can be seen as the concrete form through which capital has been able to reproduce its form of valorisation by means of the appropriation of agrarian ground-rent. The increases in the scale of production, the relative modernisation of the factories, regional integration, and so on, allowed for the partial counteracting of the increase in the technical gap and of the scale that had emerged out of the deepening of the automation of large-scale industry by means of the development of electronics. In turn, this permitted capital to take advantage of the increase in extraordinary sources of profit available in the Argentine space of accumulation. However, this ‘restructuring’ did nothing more than reproduce, at the same time, the specific limit of this form of capital valorisation, that is, its dependence upon the magnitude of those same extraordinary sources of profit and, most especially, of the magnitude of ground-rent.

Conclusion

In this chapter we offered a general vision of the development of the automotive industry in Argentina. Our principal argument was that global technical change, and the corresponding forms of the international division of labour, determined the modes of valorisation of the automotive

TNCs from the origins of the local industry up until the end of the 1950s, and not only from the, so-called, restructuring of the 1990s. Concretely, we claimed that the participation of the Argentine space of accumulation in the CIDL as a producer of agrarian commodities was complemented by the global dispersion of industrial production most associated with the NIDL. This combination of both forms of participation of the Argentine space in the global accumulation of capital took the concrete form, in the case of the automotive industry, of the development of a specific modality of the valorisation of the capital of TNCs. Namely, these firms managed to valorise normally despite operating on a small scale and with obsolete technology, through the appropriation of a portion of the abundant (albeit strongly fluctuating) ground-rent and, in certain periods, a part of the value of labour-power.

This perspective also allowed us to explain the diverse phases in the historical development of the Argentine automotive industry. In this sense we argued that the development of the integral manufacturing of vehicles in the 1960s was linked to the development of automation at the global level, due to the necessity for the TNCs to relocate their older capital in order to accelerate technical change in their home countries. In the same way we argued that the crisis confronted by the Argentine automotive industry in the 1980s was principally determined by an increase in the technological gap resulting from the deepening of global technical change, together with the relative stagnation of ground-rent. Lastly, we explained the recent expansion of the industry through global transformations in the international division of labour. On the one hand, we showed that certain general elements related to the NIDL allowed for the counteraction of the increasing insufficiency of agrarian ground-rent; for example, the way in which the regionalisation of markets allowed for a relative increase in the scale of production, or how the worsening of the conditions of exploitation of the working class provided a new extraordinary source of profit for automotive capital. We also showed that these transformations combined with the survival of aspects linked to the CIDL (in particular, the expansion of agrarian exports and, as a consequence, of ground-rent), to enable the reproduction of the ‘old’ form of valorisation of automotive TNCs in Argentina.

Sources and methodology

(1) ‘Payroll’ divided by ‘all employees’, data from Asociación de Fábricas de Automotores (various years). Calculated as average between total number of employees on 31/12 of corresponding year and total on 31/12 of previous year. Asociación de Fábricas de Automotores data excludes the parts and components industry

(2) 1960–2006: Consumer Price Index (CPI) published by Instituto Nacional de Estadísticas y Censos (http://www.indec.mecon.ar/); 2007–2013: CPI published by Dirección Provincial de Estadísticas y Censos, Provincia de San Luis (http://www.estadistica.sanluis.gov.ar/)

(3) 1960–1988: ‘Payroll’ divided by ‘all employees’, ‘motor vehicles and equipment’ industry, data from Bureau of the Census’ ‘Statistical Abstract’ (http://www.census.gov/compendia/statab/). In order to estimate motor vehicle manufacturing wages only, we have added to the source data 3 per cent for 1960–1969, 6 per cent for 1970–1979 and 10 per cent for 1980–1989, based on the wage differential between ‘motor vehicles’ and ‘motor vehicle parts’ reported by Lewis and Bauer (1964), and Bureau of Labor Statistics (1976 and 1991). 1990–2013: ‘Average hourly earnings for production workers’ multiplied by ‘weekly hours’ worked, ‘motor vehicle manufacturing’ (NAICS code 3361), data from Bureau of Labor Statistics ‘Current Employment Statistics’; we added 4 per cent to estimate ‘all employees’, based on differential between ‘production workers’ and ‘all employees’ reported in Bureau of the Census’ ‘Statistical Abstract’, various years)

(4) CPI published by Bureau of Labor Statistics

(5) Absolute purchasing power parity (absolute PPP) between Argentine peso and US dollar for the year 2005 is taken from World Bank (2008). 1960–2013 series calculated with previously mentioned CPIs. For the distinction between ‘absolute’ and ‘relative’ PPP, see Balassa (1964) and Officer (1978). For the justification of the utilisation of absolute PPP for the comparison of national real wages, see Iñigo Carrera (2007: 31–2)

(6) = (1)/(5)/(3) × 100

(7) Relative purchasing power parity (relative PPP) between ARS and USD calculated with the base period of 1960–1972, using previously mentioned CPIs. See Iñigo Carrera (2007: 31–5) for the justification of the utilisation of relative PPP for the estimation of parity exchange rates between national currencies

(8) = (1)/(7)/(3) × 100

NOTES

1. Data from Organisation Internationale des Constructeurs d'Automobiles (http://www.oica.net).
2. Note the distortion introduced by the greater proportion of workers dedicated to existing R&D activities in the core countries, which implies an underestimation of the productivity of labour effectively applied in direct production in those countries.
3. During just a few years, the automotive TNCs located a significant part of their production in the Mexican market. For example, in the period 2004–2005, 45 per cent of automobile exports were destined for Mexico. However, note that these exports are carried out in a market of preferential agreement (Acuerdo de Complementación Económica N°55) that regulates trade exchange without tariffs in the process of a regime of compensation on imports and exports, similar to that which is in effect for the regional market.
4. The Mercosur tariff is 35 per cent. The tariff is 2.5 per cent in the USA, 0 per cent in Japan and 10 per cent in the EU (López 2007: 35).
5. This term is not synonomous with 'surplus profits' (Marx 1991: 279, 300–1), insofar as the obtainment of extraordinary profits is not necessarily expressed in above normal profits, but fundamentally in obtaining normal profits despite producing in backward conditions.
6. We are assuming, for the moment, that automotive firms must purchase their means of production at least at prices of production, discounting at this level of analysis the possibility of the reduction of costs related to constant capital.
7. From 1960 to 2007 the Argentine state annually appropriated, on average, 20 per cent of the total ground-rent that flowed out of agrarian production, with peaks of 50 per cent in some periods (see Iñigo Carrera 2008).
8. See Appendix for methodological references.
9. We take the US sphere of capital accumulation as the most immediate expression of normal conditions of the exploitation of labour-power. Automotive wages in the USA were historically the highest in international terms. Other countries, as in Europe and Japan, had lower wages in the 1960s and 1970s. But these lower salaries corresponded with less qualified labour-power. In fact, Japanese and European labour-power was put into production on a massive scale only when automation simplified the labour process and enabled the incorporation of these lesser-qualified workers. Progressively (although slowly), the wage difference between the 'classic' European countries (Germany, France, and the UK) and Japan compared with the USA was reduced, as the attributes of their respective working classes tended to converge. If one takes into account that the Argentine

automotive industry tended to be backward in terms of the incorporation of technical innovations relative to all the classic industrial countries (ruling out the skill-level of labour-power as a possible explanation of Argentine lower wages), it is therefore adequate to take the US wage as an expression of the norm in the payment of labour-power or, in other words, as an indicator of the value of automotive labour-power.

10. There is insufficient data on the working day, and there are complications inherent in the separation between intensity and productivity.
11. Using the method of absolute purchasing power parity (see Appendix).
12. There certainly exist other complementary forms of the appropriation of rent by TNCs, such as direct subsidies, tax exemptions, and lines of cheap credit, all of which resulted from different regimes of promotion of the sector implemented by the national state. For reasons of space, the examination of these other forms of transfer of ground-rent to automotive capital falls outside the focus of this chapter.
13. Other Latin American countries, and Brazil especially, show similar characteristics. In contrast, the automotive industry in East Asian countries (Japan and South Korea especially) were based on the development of more modern systems of production and the emergence of new individual capitals. See Grinberg (2011) for a comparison between Brazil and Korea.
14. The transfer of complete production lines by Kaiser Motors from the USA to Argentina (and Brazil) has been well studied and documented (see MacDonald 1988, for instance), as has the use of second-hand machinery on the part of General Motors and Ford (Jenkins 1984: 52). On the other hand, a study by the Asociación de Fábricas de Automotores shows that until 1967 a quarter of the total machinery used was over ten years old, which implies that it was second-hand when the first plants were established. Other evidence which supports the same conclusion can be found in a government survey from the early 1970s (reproduced in Sourrouille 1980, Table 27), in which Ford, General Motors, Chrysler, Fiat, Citroen, and Mercedes Benz are confirmed as having built their Argentine plants through the adaptation of existing technology from their countries of origin. The most prominent studies of the industry also agree on this point (Jenkins 1984: 52; Nofal 1989: 90–1; Schvarzer 1993; Sourrouille 1980: 169).
15. Note that the productivity of labour in the Argentine automotive industry remained practically unaltered for decades (in 1990 it was only 12 per cent greater than in 1960, according to the Asociación de Fábricas de Automotores 1996).
16. It should be noted that this regression in the real wage coincided with the moment in which the automotive TNCs deepened the relative modernisation of the productive process and the reorganisation of labour relations. Between

1994 and 1998, new automotive production plants were opened and the first collective labour agreements were signed that incorporated new—more flexible—forms of the organisation of the labour process (Guevara 2010: 123).

17. According to calculations by Iñigo Carrera (2011: 56), the annual average of agrarian ground-rent between 2003 and 2010 was 53 per cent greater than between 1991 and 2001, and 83 per cent more than in 2002.

CHAPTER 9

Patterns of 'State-Led Development' in Brazil and South Korea: The Steel Manufacturing Industries

Nicolas Grinberg

The experiences of Brazil and South Korea have occupied a central place in the field of the comparative political economy of late-industrialisation. Both countries have been considered paradigmatic, since both have arguably enjoyed the strongest and deepest processes of industrial development among Latin America's and East Asia's newly industrialising countries. Most scholarship on the countries has settled on different versions of institutionalism that acknowledge the extended role played by the state in Brazil's and Korea's development processes, and which focus on the quality of state institutions as the most relevant factor in explaining their divergent experiences (Grinberg 2013a, 2014). Yet, despite their obvious differences, all mainstream accounts on the comparative political economy of Brazilian and South Korean development share one key theoretical starting-point that renders them equally incapable of fully accounting for the underlying forces. In a nutshell, they all regard the process of capitalist

G. Charnock, G. Starosta (eds.), *The New International Division of Labour*, DOI 10.1057/978-1-137-53872-7_9

development as a nation-based process and the world market as the context where the national processes of capital accumulation develop with different degrees of politico-economic autonomy.

The goal of this chapter is to offer an alternative account to the mainstream, institutionalist view on the state-led process of economic development in Brazil and South Korea, taking as its starting-point two key insights from the Marxian critique of political economy. First, that the process of capital accumulation is global, rather than national, in terms of its general dynamics and historical potencies; and, second, that inter- and intra-state political processes are forms of realisation of the process of capital accumulation on a global scale, through the specific determination of each national portion of the total capital of world society (see Chap. 2). The chapter is organised as follows. The second section advances a brief explanation of the general trends of the process of capital accumulation in Latin America and East Asia. The third and fourth sections review the main politico-economic forms of the Brazilian and Korean processes of capitalist development since the end of the Second World War (WWII). The fifth and sixth sections analyse the development of the steel industry in both countries. This industry has not only played a central role in the process of industrialisation in both countries, but has also been at the core of state actions to promote the process. For these reasons, the steel industry has figured prominently in studies of Brazilian and Korean comparative development (see Auty 1991; D'Costa 1999a, b). The final section closes the chapter with a summary of its main points and conclusions.

Global Accumulation of Capital and Development in Latin America and East Asia[1]

The development of labour productivity is the most powerful lever of the accumulation process. It results in the reduction of wages necessary for a given quantity of labour-power, extensively or intensively spent—that is, in the production of relative surplus-value. The mechanisation of large-scale industry is, in turn, the most potent form of increasing labour productivity. This process is centred on the transformation of the productive potencies of individual labour-processes into a scientifically organised, although alienated, social power (Iñigo Carrera 2013: 15–23; Marx 1976: 508–17; Postone 1996: 336–49). Yet capital makes every effort to avoid this expensive and risky process by searching for locations where particular natural or historical conditions allow it to reduce the cost of producing the commodities that are directly or indirectly consumed by the labour-force and thus increase the mass of surplus-value available for its valorisation. Hence, beyond the formal expansion of markets, the global unity of capital accumulation is only fully developed in the process of the production of relative surplus-value (Iñigo Carrera 2013: 145–51).

Originally this process centred on the search for regions where, due to uncontrollable natural conditions, primary commodities could be produced and, if their production were possible elsewhere, at a lower cost—giving place to the classical international division of labour (CIDL) (Howe 1981, 91–4; Iñigo Carrera 2013: 145–6; Marx 1976: 579–81). This form of integration of portions of the planet into the global circuits of accumulation, however, was riven with structural contradictions that determined the long-term pattern of capitalist development therein. If the total social capital managed to enhance its valorisation capacity by reducing the value of labour-power, this was then partly offset by the drain of surplus-value flowing into the pockets of landowners in the form of ground-rent (see Chap. 3).[2] Global industrial capital therefore became compelled to overcome this barrier to its own capacity to accumulate by reshaping those spaces of valorisation to recover part of that surplus-value through the establishment of an antagonistic association with local landowners. From being simply a source of cheap raw materials, these spaces of accumulation—among which Latin America figured prominently—also became determined as sources of surplus-value in the form of ground-rent (Iñigo Carrera 2013: 145–50; Grinberg and Starosta 2014: 241–2).

The accumulation of capital through the recovery of ground-rent has taken a variety of economic and political forms; all of them involving the mediation of the national state. Until the 1930s, approximately, the alliance between capital and landowners over the appropriation of ground-rent generally revolved around the production, transport, and international trade of one or more primary commodities. Then the capitals that invested in these and related sectors, as well as foreign creditors to the emerging nation-states, became landowners' main partners in the appropriation of local ground-rent. But then, from the 1930s and crucially after the end of WWII, this position was taken over by industrial capital invested in manufacturing, in whose valorisation cycle originated the bulk of the surplus-value that formed the ground-rent (Iñigo Carrera 2013: 149–52).

The modality of ground-rent recovery by capital invested in manufacturing has determined the long-term development of the process of industrialisation in these parts of the world in a specific form. In general terms, and in order appropriate ground-rent, industrial capital has had to open and close its valorisation cycle in these countries' domestic markets. With a scale of production below world-market norms, and the use of vanguard technology thus restricted, such markets have had to be protected to a degree conditioned by the amount of ground-rent available to sustain local industrial production (see Chap. 8). Industrial capital's accumulation capacity therefore has been dependent on the evolution of the ground-rent available to compensate for the ever-growing difference between local and world-market production costs resulting from the difference between local and world market scales of production.

The, so-called, process of import substitution industrialisation (ISI)–that was consolidated in most primary-commodity producing countries between the 1930s and 1950s reached its peak during the 'commodities boom' of the 1970s, and was reproduced in a limited form thereafter—has been the paradigmatic form through which this specific modality of capital accumulation has come about. In general terms, two types of indissolubly united policy-created mechanisms have shaped this process. First, state policies—such as exchange-rate overvaluation, commodity-export taxes, and regulations on primary-commodity circulation—have intervened in the turnover cycle of primary-sector capital, separating a portion of ground-rent and interrupting its flow toward landowners' pockets. These policies have channelled that portion of ground-rent to industrial capital profits—lowering the domestic prices of foreign exchange, raw materials, and labour-power—or, in a first instance, to the state. Second, other policies have enabled the effective appropriation of the separated ground-rent by industrial capital when selling in domestic markets. These have included its protection from foreign competition and direct state actions, such as the provision of inputs at below-market prices, the purchase of output at above-market prices, the enlargement of markets through overstaffing, and outright subsidies. In other words, policies associated with ISI and the political processes through which they have come about have been the specific politico-economic forms of realisation of processes of accumulation based on the appropriation/recovery of ground-rent by global industrial capital.

As in all other regions participating in the global economy as primary-commodity producers, the process of capital accumulation in Latin America has, since its origins, revolved around the appropriation of ground-rent by different social subjects, crucially its recovery by industrial capital.[3] The Brazilian economy has not been an exception to this general trend. Conversely, given the relatively large size of the local ground-rent, the process of capital accumulation in Brazil has been paradigmatic of this specific form of capitalist development (Grinberg 2013a, b).

During the last forty years, however, the international division of labour has experienced a profound transformation as a result of the process of computerisation and robotisation of large-scale industry and, especially since the mid-1970s, of the microelectronics revolution (see Chap. 4; also Iñigo Carrera 2013: 66–70; Grinberg 2013a). This leap forward in the process of automation of labour's productive attributes has greatly accelerated the internal differentiation of the collective worker in large-scale industry. On the one hand, technological transformations have involved the further expansion of the productive attributes, and hence cost, of wage-labourers performing the more complex parts of the work process. On the other hand, automation has simplified the productive functions, and hence cost, of most manual labourers remaining on the shop-floor as operators or appendages of increasingly self-calibrating and self-adjusting machines. Moreover, the new technological conditions have themselves generated a multitude of production processes still subject to manual intervention by low-skilled labourers, like the assembly, testing, and packaging of electronic micro-components and appliances (Balconi 2002; Coriat 1992; Grinberg 2013a: 180–2).

In terms of their general dynamics, those transformations in the productive attributes of the collective worker in large-scale industry have been global. Yet they have resulted in a novel differentiation of national spaces of accumulation and in the reconfiguration of the international division of labour, and hence of the production of surplus-value on a global scale. Based on those transformations in the labour process, and the associated revolution in communication and transportation methods, industrial capital has been increasingly able to disperse spatially the different parts of the labour-process according to the most profitable combinations of costs and productive attributes of the different national fragments of the global labour-force, thus giving birth to the NIDL (Iñigo Carrera 2013: Chap. 2; Grinberg and Starosta 2009; Grinberg 2013b).

As a general trend, the NIDL has revolved around the relocation of simplified labour-processes to places where industrial capital had access to labour-forces that are not only *relatively* cheap, but also whose specific productive attributes include the disciplined subordination to centrally and hierarchically organised collective labour-processes, as in the wet-rice cultivating societies of East Asia (Bray 1986: 67). Those characteristics have made the East Asian labour-force particularly productive as an appendage of increasingly automated machinery systems or in manual assembly operations; hence the region's ubiquitous participation in the NIDL and its consolidation as a global industrial power (Iñigo Carrera 2013: 63–70, 74–80; Grinberg and Starosta 2009; Grinberg 2013a).

Initially, the NIDL manifested itself in the spatial relocation of 'labour-intensive' productions, like clothing manufacturing—in which, due to the early introduction of skill-replacing technical changes the labour-force functioned as an incipient appendix of the machinery—and the electronics industries—which worked with manual-assembly operations (as identified by Fröbel et al. 1980). Through the mid-1960s, however, skill-replacing technical changes began to affect 'capital-intensive', continuous-flow production in the heavy and chemical industries, transforming manual workers in those sectors into an appendix of the machinery. A decade later, as the microelectronics revolution took hold of large-scale industry—crucially through the robotisation of assembly operations—skill-replacing technical changes began to increasingly affect 'technology-intensive', serial mechanical production in the consumer durables and capital goods industries (Balconi 2002; Brown and Campbell 2001; Coriat 1992; Ernst 2005; Hasegawa 1996). As this occurred, production in those sectors tended to move to Japan and the, so-called, East Asian Tigers—the original participants of the NIDL—and labour-power therein increased in quality and cost. Industrial capital then sought out new spaces, in the region and beyond, where it could gain access to cheaper, and equally disciplined and acquiescent, workforces for lower-skill production in the light industries and subsequently, as the dynamics of technical change allowed, in durable and capital goods production (Grinberg 2014: 719–21).

As in any other form of realisation of the process of capital accumulation on a global scale, the NIDL has come about through specific nation-level political developments. The, so-called, developmental state has been the most characteristic political form mediating the development of East Asian processes of capital accumulation as an expression of the NIDL. Despite different national singularities, all East Asian developmental states not only facilitated the outward orientation of industrial capital while nurturing infant industry. But they have also decisively pursued the political repression of the working class, thus allowing capital to purchase labour-power below its value and to differentiate the conditions of reproduction of the various parts of national workforces according to their productive attributes. Due to its sizable labour-force and early participation in the process, the experience of South Korea has been paradigmatic of this specific modality of capitalist development, through which the production of relative surplus-value on a global scale has come about (Grinberg and Starosta 2009; Grinberg 2013a, 2014).

This modality of capital accumulation has shown a remarkable developmental potency, especially in the cases of Japan and the East Asian Tigers. Yet it is not free of contradictions. Not only has the dynamism of skill-replacing technical changes resulted in an ever-deeper 'race to the bottom'. More importantly, the productive attributes upon which this specific modality of capital accumulation has rested (discipline and acquiescence) are at odds with those required from wage-labourers performing vanguard scientific research and technology/product development. This high-value creating part of the labour process, in which the development of society's productive forces comes about, has thus been relatively undeveloped in those countries participating in the global economy in this specific form.

Brazilian Capitalist Development Since World War II[4]

When WWII ended, the Brazilian process of ISI was at least half a century old. The industrial sector was then populated by a myriad of small, nationally owned capitals and a few relatively large, foreign-invested firms which had been established between the end of WWI and the Great Depression. Both types of industrial capital had grown, initially, thanks to a combination of market protection and exchange-rate overvaluation allowing them to appropriate ground-rent and, subsequently, to the collapse of international trade. Between the end of WWII and the mid-1950s, Brazilian ground-rent experienced a substantial recovery and the process of capital accumulation manifested itself in the strong expansion of local industrial production, crucially by indigenous private capital. Yet, in contrast to the pre-WWII experience, it also came about through the creation of a large number of state-owned enterprises (SOEs) and developmental banks, in some cases through the nationalisation of public utility and transport companies into which most foreign investment had previously flowed. SOE activities, combined with market-protection reinforcement and exchange-rate overvaluation, shaped the 'state-led', or 'statist', ISI process through which the appropriation of ground-rent by social subjects other than landowners, notably industrial capital, would come about (on the genesis of statist ISI, see Kohli 2004: 177–82; de Paiva Abreu 2008:

320–33). Though both types of capitals—small-private and state-owned—would subsequently support the valorisation processes of foreign-capital subsidiaries, those developments were realised through the consolidation of a nationalist state backed by the, so-called, populist alliance between the local bourgeoisie and the urban working class, especially during the commodities boom associated with the Korean War, when the ground-rent available to support the process of capital accumulation grew strongly (Grinberg 2013a).

Through the mid-1950s, however, some of the features of Brazilian capitalist development started to change when large flows of foreign-owned capital, then pursuing a new phase of global expansion, began to invest in the most dynamic parts of the local industrial sector, attracted by the substantial growth of domestic markets that enlarged ground-rent had given rise to. Unlike in the previous period of ISI, a nationalist government with an anti-foreign capital rhetoric could not politically mediate this process. Populism therefore gave way to 'developmentalism', and economic growth revived strongly (Anglade 1985: 56–7; Avelãs Nunes 1990: 188–93; Kohli 2004: 183–4; Skidmore 2007: 146–9).

Yet, despite robust growth and rapid industrial development occurring in the period to the late 1950s, the limited and contradictory dynamics of the Brazilian process of capital accumulation soon led to a crisis as the ground-rent available for appropriation contracted while primary-commodity prices collapsed in the aftermath of the Korean War. Initially, a new source of extraordinary surplus-value in the form of loanable-capital inflows began to complement ground-rent in sustaining the process of capital accumulation through ISI. Foreign credit, however, soon proved to be insufficient and unreliable (Avelãs Nunes 1990: 210–11; Frieden 1987: 99) and a third source of extraordinary surplus-value thus developed; that arising from the payment of manual workers' labour-power below its value (Zurron Ocio 1986: 8–11). This new transformation in the forms of a realisation of the Brazilian process of capitalist development did not come about smoothly. Rather, it was realised through an economic crisis that expressed the intrinsic limits of the Brazilian process of capital accumulation and the replacement of the populist alliance with a military dictatorship as its general political form of realisation (Kohli 2004: 190–210; de Paiva Abreu 2008: 349–59; Skidmore 2007:187–302).

During the 1970s Brazilian ground-rent, and the inflow of loanable capital complementing it, experienced a strong, though irregular, expansion. The production of industrial goods advanced to include complex durable-consumer goods, as well as various types of equipment and basic inputs (Batista 1992; Barros de Castro and Souza 1985). The expansion and deepening of the ISI process was manifest in sharp increases in employment and real wages in the manufacturing sector. The authoritarian regime in charge of the political representation of the process of capital accumulation thus softened its grip over the working class, while economic policies regained their developmental features through the implementation of a series of industry-wide and sector-specific promotion plans aimed at boosting private domestic capital and SEOs (Anglade 1985; Corrêa do Lago et al. 1979; Skidmore 1988) as a form of transferring ground-rent, and loanable-capital inflows, to industrial capital. The mass of surplus-value appropriated by industrial capital increased strongly and economic growth thus accelerated.

Despite these developments, through the early 1980s the Brazilian economy entered a long period of weak growth, deindustrialisation, and recurrent economic crises. Primary-commodity prices then began a process of long-term decline, only partly reversed after the commodities boom of the late-2000s, which negatively affected the growth of local ground-rent. And, although credit supply expanded on a global scale thereafter, as 'developed-country' states have increasingly attempted to sustain consumption through easy-credit policies, loanable-capital inflows to Brazil have been irregular. To begin with, these were only re-established in the early-1990s, when the global supply of credit had grown sufficiently to, once again, reach non-'core' economies. Secondly, the expansion of global credit itself has not been constant. On the contrary, it has proceeded in a succession of periods when easy-credit policies resulted in loose monetary conditions that fuelled global growth, punctuated by periods when credit policies became more stringent as a means of addressing ensuing inflationary pressures (Brenner 2006: 143–63, 267–343; Iñigo Carrera 2013: Chap. 6).

The relatively slow growth of the combined mass of ground-rent and loanable-capital inflows led to a partial reversal in the process of state-led ISI through which their appropriation by industrial capital had come about. In other words, as these sources of extraordinary surplus-value reduced, relative to the demands placed upon them by industrial capital looking to valorise normally, state policies channelling them were partly or fully withdrawn. Market protection was reduced for some sectors and eliminated for others while SOEs were privatised. Neoliberalism thus replaced developmentalism as the general political and ideological form of realisation of the Brazilian process of capital accumulation which, nevertheless, continued to revolve around the recovery of ground-rent by global industrial capital.[5] In the post-1980 period, therefore, the state-led process of ISI became increasingly more limited, and industrial capital began to find a new source of extraordinary surplus-value to complement the ground-rent and loanable-capital inflows, the general payment of labour-power below its value.

The neoliberal restructuring of the ISI process started, incipiently, in the early-1980s, during the last years of the military government, and its deepening became the task of successive post-1990 democratic governments. After a decade-long weak economic performance and worsening labour-market conditions, there was no longer need for capital to rely on—politically expensive—authoritarian solutions to lower wages, deal with unemployment-related unrest, and divest state assets at fire-sale prices—all of which have been forms of realisation of the Brazilian process of capital accumulation during the period of *relatively* low rent.

Korean Capitalist Development Since World War II[6]

During the two decades following the end of WWII, the structure of the Korean economy did not qualitatively differ from Brazil's, where capital accumulated through the recovery of ground-rent. This specific modality of capital accumulation came about, as in Brazil and elsewhere, through a set of state policies ‘promoting’ ISI. The singularity of the Korean ISI process resided in the fact that the limited available ground-rent was complemented with a portion of small agrarian capital’s profits and foreign-aid inflows. The limited character of the Korean ISI process, especially *vis-à-vis* the Brazilian experience, thus resulted from the relatively small size of extraordinary surplus-value available to support industrial capital’s valorisation process (on the Korean ISI process, see Frank et al. 1975; Krueger 1979: Chap. 2).

Through the mid-1960s, however, the Korean process of capitalist development began to experience a structural change, as a result of the aforementioned transformation in the production of relative surplus-value on a global scale leading to the NIDL. Between the mid-1960s and the mid-1970s changes in the Korean economy resulted largely from the continuous appreciation of the Japanese industrial workforce as the global process of capital accumulation transformed Japan into a producer of consumer-durable goods, industrial inputs, and equipment. The Japanese labour-force was then increasingly replaced by new sources of relatively cheap and disciplined labour-power available in East Asia, which was capable of performing simple manual labour-processes in the textile, apparel, and electronics industries. After the mid-1970s, the transformations experienced by the Korean economy resulted not only from the further appreciation of the Japanese labour-force, but also, and crucially, from the direct impact of the contemporary processes of skill-replacing technical change, initially in process industries like steel and chemicals and subsequently, especially after the microelectronics revolution, in such serial production sectors as motor-vehicles, home appliances, and consumer electronics. Moreover, the Korean labour-force thereafter became itself a direct product of the process of capital accumulation; its quality was, thus, continuously improving through on-the-job experience and, increasingly, state mediation. As economic activity moved into higher value-adding sectors, the production of surplus-value expanded and the process of economic growth accelerated (Iñigo Carrera 2013: 76–82).

Three types of policy sets thus mediated the structural transformation of the Korean process of capitalist development throughout the 1960s and 1970s. First, some policies enhanced the export orientation of local industrial capital; second, other policies accelerated both the concentration of industrial capitals and the extent to which they became capable of normal world-market production; and, third, some policies mediated the reproduction of the local workforce with the characteristics and price needed for such activities. In general terms, the degree of direct state regulation of the Korean economy increased as the process of capital accumulation on a global scale changed the conditions of valorisation of capital in Korea in the direction of 'fixed-capital-intensive' industries like durable-consumer and heavy-industry goods. A relatively economically 'liberal', yet politically repressive, state mediated the emergence and initial development of the Korean export-oriented industrialisation (EOI) process during the 1960s. This process required large amounts of low-cost, unskilled labour-power and relatively low-cost fixed-capital investments. The provision of state guarantees for local firms' international-borrowing activities (for example, in the textile industry) and the establishment of foreign-capital subsidiaries (for example, in the microelectronics industry) were then sufficient to develop industrial capital for world-market production. In contrast, the emergence and subsequent development of durable-consumer goods and heavy-industry sectors came about through the consolidation of a nationalist 'developmental state' that not only disciplined while upgrading labour, but also accelerated the concentration of industrial capital to reach world-market scales, either through the provision of credit to private firms by state-owned banks or, as in the case of the steel industry, the centralisation of capital under direct public ownership. Moreover, policies protecting the long-maturing industries replaced the more liberal trade regime prevailing during the initial, light-industry-based stages of the Korean EOI process (for policy analyses, see Kohli 2004: 87–122; Krueger 1979: 99–138; Michell 1988: 61–8).

As in many other 'developing' countries, the early-1980s global recession triggered a process of financial sector and foreign trade liberalisation in Korea. However, unlike in Brazil and Latin America generally, this was not a political expression of the inability of the local ground-rent to sustain a diversified, domestic market-oriented industrial capital (Grinberg 2010). The strong growth and development of the Korean EOI process continued after the 1980–1982 recession, even in the context of raising wages. Liberalising reforms in Korea were, in the main, an expression of two other trends. First, the maturation of parts of its industrial sector which no longer required extended market protection and state support for their normal reproduction (for example, light industries). Second, the phasing out of other parts that proved to have had limited commercial potential (for example, aluminium and heavy-machinery industries) and of excessive productive capacity in potentially viable sectors (for example, shipbuilding). Meanwhile, during the 1980s, 'nascent' industrial sectors (for example, microelectronics and motor-vehicles) continued to be strongly supported by the state (Chang et al. 1998: 740; Green 1992: 416; Mathews and Cho 2000: 119–35), while, at the same time, developing the capacity to compete in world markets on the same basis as the large-scale heavy and chemical industries—namely, through the use of a *relatively* cheap and disciplined labour-force for simplified productive processes (Bello and Rosenfeld 1992: 113–18; Williams et al. 1994: 61–3).

Neoliberal reforms in Korea also contrasted with contemporary OECD country experiences, where they mediated the differentiation in the conditions of reproduction of the various fragments of the local industrial labour-force (see also Chap. 7). During most of the 1980s, wage differentials among Korean industrial workers declined, albeit from a highly unequal base (Lee and Lindauer 1997: 60–4). Manual workers' wages increased strongly across the board as the industrial base 'deepened', and so did the demand for more skilled labour-power that could no longer reproduce itself normally under wage conditions corresponding to its peasant origin. This process came about through a period of political opening up and the sharp, though short-lived (1987–1990), increase in working-class activism, crucially by core manual workers (Koo 2001: 153–87).

During the 1990s the Korean economy continued its growth process and its path of 'upgrading' to high-technology industries (Mathews and Cho 2000: 135–47), as a form of realising the production of relative surplus-value on a global scale through the NIDL. Though this new deepening of Korea's industrial sector resulted from the same global-scale economic forces as the previous development of light and heavy industries, it required a lower degree of direct state regulation of productive activities. As industrial capital matured, reaching world market standards, both market protection and the state's support of private-firm funding activities were no longer necessary. On the contrary, capital-account liberalisation became necessary to capture a portion of the expanding global credit supply, which was vital in funding the rapid upgrading of Korean industrial firms in light of emerging competition in world markets from firms located in countries with large supplies of cheaper and, arguably, equally disciplined labour-power (such as in China and Southeast Asia). As an expression of the economic transformations at stake, the 'neoliberal state' replaced the developmental state as the general political representative of the South Korean process of capital accumulation (Shin 2003: 136–70).

Although economic growth remained strong during the 1990s, these developments—that is, the surge of new competitors in global markets and the increasing reliance on external debts to fund investments—expressed the inherent limitations of the Korean process of capital accumulation. Indeed, when in the late 1990s the global process of overproduction of capital became manifest in the East Asian crisis, and demand for Korean exports slowed markedly, while the supply of credit to 'emerging markets' retrenched sharply, the South Korean economy entered its most severe crisis since the end of the 1950–1953 Civil War (Grinberg 2015). And, though in the post-crisis decade the Korean economy underwent a strong export-led recovery that was manifest in further industrial deepening, this process was, unlike in previous periods, supported with a strongly undervalued currency and an increasing, rather than decreasing, degree of labour-market fragmentation and precariousness (Chang and Chae 2004; Moon and Rhee 2009).

The Brazilian Steel Industry[7]

Brazil has a long history of large-scale integrated production of steel. Import substitution efforts in the sector began in the 1930s and expanded significantly during the 1940s under active state promotion. In 1941, after plans for the creation of a privately run project with foreign capital participation failed, the state-owned Companhia Siderúrgica Nacional (CSN) was finally incorporated. Five years later, Latin America's first fully integrated steel mill was completed in Volta Redonda, Rio de Janeiro, close to the country's major industrial areas and iron ore mines (Baer 1969: 68–79; Dahlman 1978: 34–9, 94–5; Fisher et al. 1988: 166–8).

State intervention in the industry increased during the 1950s developmentalist drive with the creation, and subsequent expansion, of a number of companies and plants, including Cosipa in Sao Paulo and Usiminas in Minas Gerais. Though controlled and partly funded by regional governments, these, as with CSN before, received substantial amounts of federal resources channelled through the National Development Bank (BNDE). Usiminas also incorporated the participation of Japan's Nippon Steel (Amarante de Andrade and da Silva Cunha 2003: 5; Dahlman 1978: 40–9).

As in many other developing countries, the declared goal of Brazilian steel SOEs was not only to achieve self-sufficiency in such a critical product for industrial development and national defence, but also to support downstream industries, like machinery, motor-vehicles, shipbuilding, construction, and railways; all of them key sectors in the ISI programme (Amann et al. 2004: 9; Baer 1969: 83; Fisher et al. 1988: 226). The economic content of that policy, however, differed from its ideological forms of realisation. State-owned steel mills in Brazil would act, as all other SOEs, as a medium for the transfer of ground-rent from landowners to industrial capital, crucially by selling subsidised outputs, buying inflated inputs, and by employing an overextended workforce. Moreover, but in contrast to other SOEs, they would also became an active medium for the transfer of ground-rent to industrial capital materialised in the price of iron ore, which was substantial given the country's large availability of low-cost, high-grade mineral deposits. A dual structure thus developed in the Brazilian steel industry, with state-owned integrated mills specialised in flat products, and private firms, mostly operating electric-arc furnaces, specialised in long products and using low-cost raw steel supplied by the former as their main input (Amann et al. 2004: 10). Under these structural conditions, the industry's development depended thereafter on the evolution of ground-rent, complemented by foreign credit, available to support the limited process of capital accumulation.

After growing rapidly for almost two decades, in the early 1960s the Brazilian steel industry, and in particular the state-controlled sector, entered a period of sluggish growth, as did most of manufacturing. As explained above, the growth of ground-rent then stagnated while external credits dried up. The downturn, however, was short-lived. By the end of the decade, the, so-called, Brazilian economic miracle was underway and the steel industry thrived again while resources to fund state investment were enlarging. In 1971 the long-delayed National Steel Plan was launched to coordinate investment and consolidate the sector to take advantage of economies of scale. To this end, it intended to create a holding company to embrace all SOEs and the National Steel Fund to finance the sector's expansion, although this never fully materialised. The Plan also reaffirmed the market division between state and private firms, and aimed to use 20 per cent of local capacity for export production (Amarante de Andrade and da Silva Cunha 2003: 5–6; Dahlman 1978: 95–8).

By the mid-1970s, the sector's recovery gained momentum and entered a second period of heavy investment. With ground-rent and credit inflows growing strongly again, steel companies received substantial state support under the auspices of the Second National Development Plan (NDP II 1975–1979) that aimed to promote further substitution of industrial inputs and capital-goods imports. In 1975 all steel SOEs finally came under the control of the holding company Sidebras, which, subsequently, also absorbed a number of small privately owned firms manufacturing specialty products (Dahlman 1978: 98–103). Large investments in productive facilities were thereafter undertaken by both state-owned and private-sector firms (Amarante de Andrade and da Silva Cunha 2003: 9). In the state sector the 1970s saw not only the further expansion of CSN, Usiminas, and Cosipa, but also the establishment of two new large mills, Tubarão Steel Company (CST) and Açominas. The former, a joint venture between the Brazilian state, Japan's Kawasaki Steel and Italy's Finsider, was constructed following the Japanese/Korean model in the coastal city of Vitoria with the purpose of exporting semi-finished slabs (D'Costa 1999b: 6–8). The latter was to produce finished and semi-finished products for both domestic and export markets. During this period, several wholly privately-owned firms also emerged, while others expanded their operations (Amann et al. 2004: 10; Dahlman 1978).

The Brazilian steel industry suffered in the debt crisis of the early 1980s, along with the rest of the manufacturing sector. Yet, by the mid-1980s, it was at the forefront of a short-lived export-led economic recovery that prompted several commentators to claim that the investments undertaken through the NDP II had finally succeeded in transforming the structure of the Brazilian economy by creating a self-sufficient, internationally competitive industrial sector (see Barros de Castro and Souza 1985). The reality of the Brazilian economy, however, could have not been more different, as the case of the steel industry makes clear. Labour productivity remained low by world-market standards and thus labour costs remained high, partly due to the low level of equipment automation and partly due to overstaffing in state-owned mills. Though the industry's expansion under the auspices of, and massive funding received from, the NDP II had allowed Brazilian steel SOEs to attain the lower end of the theoretical minimum efficient scale of production, this was well below the scale of Japanese and Korean plants with which they were competing (D'Costa 1999a: 89, 97; Fisher et al. 1988: 300). International markets could only be conquered thanks to a strong undervaluation of the national currency prevailing in the mid-1980s, the low local cost of iron ore and hydroelectricity, and the export subsidies that remained in place.

As can be observed in Table 9.1, in 1985 Brazilian average operational costs for the production of steel were, at exchange rates that reflected the relative evolution of the local currency to reflect value, substantially above those in Japan, Germany, and Korea. When depreciation expenses are considered, this cost disadvantage worsened further as Brazilian integrated mills had been purchasing equipment and contracting construction services from local companies at substantially inflated prices (Mendes de Paula 1993: 46). During the late 1960s, and crucially the 1970s, the local supply of highly-priced industrial equipment increased substantially under the auspices of various programmes implemented to deepen the ISI process, including the market reserve granted to local manufacturers (Amann 1999: 338–9). While construction costs of Korea's POSCO plant averaged USD500 per 1000 tons of annual production capacity, they reached USD1000 in Açominas and USD3000 in CST (D'Costa 1999b: 99).

The combination of high fixed-capital costs, overstaffing, and low-priced output affected the profitability of Brazilian steel SOEs. In 1985 the profit rate was –3.5 per cent for Açominas, producing a mixed output mainly for the domestic market, and –0.83 per cent for CST, producing slabs mostly for external customers. Their profit rates in the mid-1980s

Table 9.1 Cost of producing cold-rolled coil (USD per ton of finished product)

[a] Parity exchange rates

[b] State-of-the-art facilities

Sources: data from Barnett and Crandall (1986); *World Steel Dynamics* (various issues) would have been around 16.3 per cent and 6.8 per cent, respectively, were these companies paying international prices for their fixed-capital investments.[8]

During the late 1980s and early 1990s, the Brazilian process of capital accumulation through ground-rent recovery underwent a structural crisis and would begin to reproduce itself under new politico-economic forms—namely, a limited or neoliberal ISI process. As part of that transformation, steel SOEs were privatised or shut down. They would no longer mediate the appropriation of ground-rent by industrial capital.

The 1990–1992 privatisation process gave way to the partial consolidation of the steel industry and, consequently, the rationalisation of employment practices and the upgrading of productive facilities (Amann and Nixson 1999: 76–8; de Andrade and da Silva Cunha 2003: 16). Labour productivity strongly increased, yet remained well below world-market norms, as most plants continued producing on a suboptimal scale and technological level. Hence, while through the mid-1990s the Brazilian steel industry became a global low-cost producer of low technology-intensive hot-rolled steel, its international competitiveness was based on the low local cost of iron ore, energy, and labour-power, and the relatively lax local environmental regulations (Amann and Nixson 1999: 69–79; McKinsey 1998: 28).

Moreover, despite early gains in international competitiveness, throughout the 1990s the Brazilian steel industry became, once more, increasingly oriented to the domestic market. As the decade progressed, exports fell below 30 per cent of total output, and became concentrated in semi-finished products, like slabs produced by CST and Açominas, and/or directed to protected regional markets (Instituto Brasileiro de Siderurgia 1995, 2000). The increasingly high overvaluation of the national currency, together with the high cost of local transport and port facilities, hurt the profitability of exported goods, other than raw or semi-processed materials (Mendes de Paula 1993: 52–3; McKinsey 1998: 13, 27, 34). In the steel industry, exports of high value-added products were only possible because of tax credits and subsidised loans made through the BNDE's modernisation fund for equipment acquisitions, which compensated for the negative impact of exchange-rate overvaluation on local costs other than raw materials (Amann and Nixson 1999: 81; Amarante de Andrade and da Silva Cunha 2003: 14–6). Exchange-rate overvaluation, nevertheless, reduced the domestic price of iron ore and imported equipment, largely possible after the 1990–1994 trade-opening reforms, and thus allowed, now privately-owned, steel producers to appropriate ground-rent when selling their output in the domestic market.

Unsurprisingly, the sector's profitability improved significantly in the post-privatisation period. First, employment in the steel industry was reduced by as much as 37.6 per cent during the 1989–1994 privatisation process and subsequent adjustment. Secondly, steel SOEs were purchased at prices far below the real value of their assets (Amann et al. 2004: 15, 31). In 1995, the return on capital invested in Brazilian steel producers was 3.6 per cent, 10.2 per cent and 23.4 per cent when calculated at, respectively, 'replacement cost', 'current market value' and 'privatisation values' (McKinsey 1998: 29).

After the 1999–2002 global and local economy slowdown, the Brazilian steel industry went through another process of consolidation, which included the entrance of major global leaders, like ArcelorMittal that bought CST and other smaller plants, and the fusion of domestically owned firms (for example, the consolidation of the Gerdau Group to take over Açominas, among others). This process resulted in significant investments in technological upgrading and the expansion of production capacities, both heavily supported by BNDE subsidised loans (Amarante de Andrade and da Silva Cunha 2003: 17–20). Yet despite these developments, no integrated mill in Brazil managed to achieve world-market scales of operation and, arguably, technological/environmental standards. Furthermore, the post-2004 increasing exchange-rate overvaluation—the general form of ground-rent transfer to industrial capital—significantly hurt export growth, notably of high value-added products, maintaining structural limitations on the expansion of the market and therefore on the introduction of vanguard technology (McKinsey and Co. 2013: 15). In 2008, Brazil's indirect trade in steel became negative for the first time since the mid-1970s, while locally owned firms took advantage of the strong exchange rate overvaluation to invest in facilities in industrially advanced countries (World Steel Association 2013).

In sum, before they were privatised in the early 1990s, steel SOEs, controlling almost all integrated facilities and the manufacture of flat products, played a central role in the promotion of the ISI process (that is, in the accumulation of capital through ground-rent recovery). They supplied steel products to their clients at subsidised values, purchased equipment and machinery from domestic producers at inflated prices, and employed an overextended workforce. The resources used to provide these subsidies originated not only in the profits of these companies but also in the ground-rent appropriated, and the foreign capital borrowed, by the state. In the post-privatisation period, steel companies no longer channelled a portion of the agrarian rent and external credits to their suppliers and clients. They continued, however, to mediate the appropriation of the rent materialised in the price of iron ore and hydroelectricity to steel producers and consumers (that is industrial capital, notably the automobile and white-goods sectors). Moreover, capitals invested in integrated steel mills themselves began, along with any other private capital in Brazil, to participate in the appropriation of local ground-rent and its complementary sources of extraordinary social wealth.

The Korean Steel Industry

In the mid-1960s, the Korean steel industry was practically non-existent. Private domestically owned firms, utilising obsolete facilities and a large amount of imported pig iron and scrap steel, satisfied around one-third of a limited domestic demand. Despite the ambitions of the Korean military government, there was not a single large-scale integrated mill, let alone an internationally efficient plant or quality steel producer. There were already three in Brazil at that time (Amsden 1989: 295; Cohen 1978: 422; D'Costa 1994: 52; Fisher et al. 1988: 168; Hogan 2001: 39).

The shape of the Korean steel industry, however, would soon change dramatically. In an import-substitution effort, and against the advice of foreign governments and international development agencies, the Korean state began to plan for the construction of a large-scale fully-integrated steel mill. This was allegedly necessary to help develop a 'balanced' industrial base, including the military industry needed to protect the nation from the security threat permanently posed by North Korea, and crucially after the change in US security policy on East Asia (Amsden 1989: 295; Clifford 1998: 67–71; Haggard 1994: 33–4).

In late-1960s Korea, however, such an enterprise was not a straightforward project. To being with, it was a project that required an amount of capital that no local private company could then hope to raise. And, even if this were otherwise, the local private sector was unwilling to risk resources in an industry that, given its importance for the process of industrialisation and national defence, could easily fall under strong government regulations (Park 2003: 67–8). Moreover, despite the government's efforts, foreign companies were not prepared to undertake such a supposedly unviable project (D'Costa 1994: 56; Hogan 2001: 3–10).

As in most other ‘developing’ countries, and many ‘developed’ ones, the state as the political representative of Korean social capital therefore took charge of the project and, in 1968, created POSCO (Pohang Iron and Steel Company) using its own and externally borrowed resources (including funds from Japanese war reparations). Later on, the company received a strong boost as part of the 1973 Heavy and Chemical Industries Plan. POSCO has since been the main Korean producer of high value-added flat products and, until recently, the only one with integrated facilities. All privately-owned mills have used electric-arc furnaces to finish the raw steel mainly bought from POSCO (D’Costa 1999b: 84).

The construction of POSCO’s first plant in the deep-water, southeast coastal city of Pohang was completed in five stages between 1970 and 1984. For this project, POSCO contracted most technology and technical assistance from global market leader Japan’s Nippon Steel, though it also sourced key parts of its equipment in Europe. The low cost of the local labour-force and the militaristic discipline used in the process maintained construction costs at internationally low levels (Amsden 1989: 297; Auty 1991: 19–20; D’Costa 1994: 58–60; Hogan 2001: 15–25). In contrast to the Brazilian experience, POSCO has always sought to purchase its fixed capital at the lowest prices possible, regardless of national origin. Production capacity in 1985, when POSCO’s first plant was finally completed, reached 9.6 million tons per year, well above the theoretical minimum efficient scale of 3.5 and almost equal to the average of the Japanese industry (Barnett and Schorsch 1983: 57–9). During the first stages of its history, POSCO concentrated on the production of heavy plates and hot-rolled coils used in the rapidly expanding shipbuilding, automobile, and machinery industries. More skill-intensive products, like cold-rolled coils and specialty steels, were relatively unimportant in the initial stages of POSCO’s development (Park 1997: 14–16).

POSCO’s fast ascent has strengthened those scholarly positions which point at state institutions as the main factor accounting for Korea's late-industrialisation (see, for example, Amsden 1989; Kohli 2004). This, however, is only a superficial part of the story. Often forgotten in those analyses is the fact that during the 1970s and 1980s the steel industry was being affected by the continual introduction of skill-replacing technical changes,[9] and that Korea had access to a low-cost, highly-disciplined and easily-trainable workforce—crucially after a two-year long compulsory military instruction for male workers and extended state repressive activities and indoctrination campaigns (Bello and Rosenfeld 1992; Grieves and

Saul 1986: Chap. 2). Moreover, existing labour market institutions, such as the extended use of subcontracting and null or weak trade-union representation, have been particularly propitious in reproducing a workforce with the combination of productive attributes and cost required by capital in the industry (D'Costa 1994: 68–9, 1999b: 105–6).

By the early 1980s, with the completion of the third expansion stage, the company was successfully competing with Japanese integrated mills, the contemporary lowest-cost producers, in world markets for finished steel—at least in non-specialty products (Auty 1991: 20). In sharp contrast to the Brazilian experience, during the 1970s and 1980s POSCO sold about half its output in the world market and most of the remainder to local, export-oriented sectors, such as the shipbuilding, machine-tools, and automobile industries (Hogan 2001: 37–61). Through the sale of steel to local consumers at subsidised prices, POSCO transferred a portion of its profits to these privately-owned downstream industries, helping them to strengthen their international competitiveness (Auty 1991: 24; D'Costa 1994: 69–70, 1999b: 87; Park 2003: 55). Hence, the alleged private-style management of this SOE cannot be held up as the reason behind its long-term commercial success, as argued elsewhere (see, for example, D'Costa 1994; Park 2003: 68–9). Nor can it be the quality of state institutions—the largely state-owned Korea Aluminium Company, for instance, was unable to replicate POSCO's success (Stern et al. 1995: 140–2).

Skill-replacing technological developments resulted in changes in the international competitiveness of capitals located in different countries, and hence in the international division of labour in steel production. As can be observed in Table 9.2, in the mid-1980s POSCO's operational costs for hot-rolled coils were lower than the average Japanese producer and roughly the same as those of a state-of-the-art Japanese plant. POSCO compensated for the lower productivity of its workforce, which was largely

Table 9.2 Cost of producing hot-rolled coil (USD per ton of finished product in 1985)

	Japan	*Korea*
Major raw materials	94	84
Labour costs	41	18
Non-major raw materials	54	47
Total operating costs	189	149

Note: administrative and financial costs not included

Source: Data from Grieves and Saul (1986) attributable to its relative inexperience and the less efficient technology used for casting processes, with lower wages (see Table 9.1). Japanese leading firms retained, at least for a period, a marginal cost advantage in the more technology-intensive cold-rolled coil production. POSCO’s competition eroded some of Japanese firms’ external markets, contributing to their excess capacity, as had happened a decade earlier to US mills when Japanese capital appeared in the global market for steel. This further increased their total average production costs, undermining their long-running international competitiveness. While POSCO attained 99 per cent capacity utilisation during the mid-1980s, the largest Japanese steel companies averaged only 52 per cent (Park 1997: 14).

These transformations in the global steel industry manifested themselves in differences in the valorisation and growth capacities of capitals invested in large-scale integrated mills in both countries. While the rate of profit for an average steel mill in 1985 Japan was about 8.45 per cent, POSCO’s pre-tax profit rate would have been around 20 per cent had it not sold part of its output in the domestic market at substantially subsidised prices. Conversely, the pre-tax rate of return on capital advanced for valorisation for a representative Japanese steel mill that year would have been around 26 per cent had they worked at full capacity and thus spread fixed costs more thinly. More importantly, POSCO’s rate of profit (at export rather than domestic market prices) in 1985 would have been around –2.3 per cent had it paid Japanese wages to its relatively low-productivity production workers.

As can be observed in Table 9.1 the slight advantage enjoyed by Japan’s most efficient steel mills disappeared throughout the second half of the 1980s, when POSCO installed its third continuous caster at the Pohang works, thereby attaining a 100 per cent continuous casting process, when it also built its state-of-the-art, fully automated and computerised plant in the southern coastal town of Gwangyang (Hogan 2001: 25–35; Park 2003: 61–2). Nevertheless, despite becoming one of the largest and most efficient steelmaking companies in the world, POSCO has not been at the forefront of technological developments in the sector. Rather, the company has concentrated on the introduction of incremental rather than radical innovations (Hogan 2001: 63–73; Park 2003: 56–60).

During the 1990s POSCO consolidated its world leadership and managed to out-compete the most efficient Japanese producers in almost every sector of the market (see Table 9.1 for the case of cold-rolled coils). As the new technological base was consolidated and worker experience matured, labour productivity in Korea as good as reached Japanese levels, while wages remained substantially lower (Park 1997: 14). Moreover, even after the revival of the US steel industry led by the mini-mill sector, POSCO could, unlike most of its Japanese counterparts, continue to compete successfully in world markets for non-speciality steel (Park 2003: 53–4). The company's rate of profit, when output is valued at world market prices, remained at around 25 per cent in 1995 despite the emergence of a new global steel crisis.

With POSCO's global leadership consolidated, the Korean state initiated its divestment from the company as part of an economy-wide liberalisation programme. The firm had by then already attained an efficient scale of operation and had become one of the world's largest and lowest-cost steel producers. Moreover, downstream industries were no longer in need of heavily subsidised steel products as they had also substantially improved their international competitiveness. On both sides, there was no longer a need for public ownership of the company. Yet, POSCO's sale was, unlike that of its Brazilian counterparts, a slow process; it only ended in 2001, when the state sold its remaining 20 per cent to 25 per cent of the company's equity. By the mid-2000s at least two thirds of the company's shares were owned by foreign investors (D'Costa 1999b: 101; Hogan 2001: 16).

Although POSCO's cost competitiveness in global markets remained strong during its post-1998, privately run era, it has not been as comfortable as before. As wages in South Korea increased, while local workforce skills expanded further, the cost gap with producers in both higher-wage/productivity and lower-wage/productivity countries narrowed. As Table 9.1 shows, in 2003 operational costs for the production of cold-rolled coils at parity exchange rates—that is, discounting the post-crisis undervaluation of the Korean currency—were still lower than in industrially advanced countries but already higher than in China where, nevertheless, steel products are arguably of a lower quality. This, however, might be misleading because the Chinese *yuan* was also widely considered to have been strongly undervalued (Grinberg 2014). At market exchange rates, POSCO's operational costs were still lower than Chinese costs.

In sum, the emergence and long-term development of the South Korean steel industry was not simply a product of bold state policies, as is often argued. Rather, it resulted from the development of the autonomously regulated process of capital accumulation on a global scale, whose contradictory motion has been necessarily *mediated* by the actions of the Korean state. In effect, the Korean state's long-term efforts in the promotion of the sector only began to pay-off after the mid-1970s, when the development of the NIDL created the conditions for capital to take advantage of the large availability in Korea of relatively cheap, highly disciplined, and easily trainable labour-power. More specifically, automated and computerised technologies had by then significantly simplified production processes and thus made possible the use of relatively low-skilled workforces. Before the mid-1970s state policies had been as ineffective in building an internationally competitive steel industry as in many other developing countries.

Conclusion

This chapter has compared the processes of ‘state-led’ industrialisation in Brazil and South Korea. It claimed that the specific form of participation of each economy in the production of relative surplus-value on a global scale has determined the pattern of industrialisation that followed and the political processes through which it came about. In Brazil industrial capital accumulated through the state mediated recovery of ground-rent, which implied small-scale production for protected domestic markets. By contrast, in South Korea, industrial capital accumulated through the exploitation of a *relatively* cheap and disciplined workforce performing simplified activities for world market production in increasingly complex sectors. These claims were substantiated with the analysis of the differentiated development of these countries’ steel industries.

Notes

1. This section draws upon on Iñigo Carrera (2013), Grinberg and Starosta (2009, 2014), and Grinberg (2013b).
2. Ground-rent is surplus-value appropriated by landowners due to their differential and absolute *monopoly* over uncontrollable natural conditions of production that, respectively, increase labour productivity or make production possible (Marx 1981: 779–823).
3. The structure of the process of capital accumulation in Mexico and Central America was transformed in the 1980s as a result of the same economic forces that accounted for the emergence of East Asia as a global industrial powerhouse (Grinberg 2010).
4. This section is based upon Grinberg (2016).
5. As in the industrially advanced economies, neoliberalism has also been the politico-economic form through which capital realised the differentiation of the conditions of reproduction of the different portions of the workforce

according to their, increasingly distinctive, productive attributes (Iñigo Carrera 2013).

6. This section is based on Grinberg (2013b and 2016).
7. The following two sections draw upon Grinberg (2011: 115–33).
8. See Iñigo Carrera (1996) for the theoretical and methodological foundations of the model used to measure the profitability of individual industrial capitals; and Grinberg (2011: 181–3) for the sources used to pursue the computations of representative capitals in the Brazilian and Korean steel industries.
9. Skill-replacing technical changes in the steel industry centred, initially, on the computerisation of the control of the physicochemical processes required to transform raw materials into final products and, subsequently, on the automation of the regulation and interconnection of such processes (Balconi 2002; Coriat 1992; Hasegawa 1996).

Acknowledgements

This book has been in the making for quite a long time, although in two clearly distinct stages. In its first 'incarnation', it resulted from my doctoral research in the Department of Sociology at the University of Warwick under the supervision of Simon Clarke and Robert Fine, who kindly provided advice, intellectual inspiration and support throughout my PhD studies. During those years, and despite geographical distance, I benefited greatly from discussions of many of these ideas with my good friend Axel Kicillof. The thesis was defended in mid-2005, but sat on my desk waiting to be reworked and expanded into this book until 2013, when, back in my home country (Argentina), and after 10 years in the UK, I managed to find the time, intellectual motivation and 'peace of mind' to resume work on the manuscript. However, between those two periods I continued thinking through many of these issues, and also had the chance to discuss them fruitfully with numerous people, who offered insightful comments and criticisms that helped me improve and sharpen the presentation of my argument.

Among those from abroad, I would like to thank Greig Charnock and Tom Purcell, who I met while working at the University of Manchester and who have always been very encouraging about this book project. Also, I would like to thank members of the International Symposium on Marxian Theory, who have invited me to join their annual meetings since 2008, an invaluable scientific forum for methodologically informed debate on fundamental issues in the critique of political economy. I am also grateful to Peter Thomas and Sebastian Budgen from the editorial board of Historical Materialism, who have been very supportive of this book project.

Back in Buenos Aires, many other friends and colleagues contributed with feedback on earlier drafts of this work. In particular, I would like to mention Gastón Caligaris, Tomás Friedenthal, Alejandro Fitzsimons and Nicolás Perez-Trento, who very enthusiastically agreed to set up a 'reading group' that discussed preliminary versions of each of the chapters, and who provided very detailed and pertinent comments on all of them. More broadly, I wish to thank all comrades at the Centre for Research as Practical Criticism (Centro para la Investigación como Crítica Práctica) who have helped sustain a stimulating political milieu in which to debate these ideas. Finally, I am deeply grateful and indebted to Juan Iñigo Carrera, who, as a politically committed and devoted teacher, has shared his vast knowledge with utmost generosity and solidarity over the past 17 years.

Chapter 3 incorporates material from 'Which "Rational Kernel"? Which

"Mystical Shell"? A Contribution to the Debate on the Connection between Hegel's Logic and Marx's Capital', in *Hegel's Logic and Marx's Capital*, edited by Fred Moseley and Tony Smith, Leiden: Brill, 2014: 89–111.

An earlier and shorter version of Chapter 4 appeared in 2008 as 'The Commodity-Form and the Dialectical Method: On the Structure of Marx's Exposition in Chapter 1 of *Capital*', *Science and Society*, 72(3): 295–318.

Parts of Chapter 8 include material from 'The system of machinery and determinations of revolutionary subjectivity in the *Grundrisse* and *Capital*', in *In Marx's Laboratory: Critical Interpretations of the Grundrisse*, edited by Riccardo Bellofiore, Guido Starosta and Peter Thomas, Leiden: Brill, 2013.

This book is dedicated to my wife Nara and my children Oliverio and Lola: without your love and affection, this book would never have seen the light of the day.

Introduction: On the Current State of Revolutionary Theory

The topic of this book is emancipatory subjectivity. More precisely, it is a scientific inquiry into the social determinations of the revolutionary subjectivity of the working class. Given the current state of radical intellectual labour, this may sound like an outmoded, if not directly courageous but hopeless, subject of research. In effect, since some intellectuals proclaimed that the time had come to wish farewell to the working class,[1] critical social theory has not ceased moving away from the notion that the working class is the social subject whose revolutionary action will put the alienation inherent in the capitalist form of social life to an end. As Iñigo Carrera vividly puts it, critical social theory moved from seeing the working class as the social subject meant to abolish the capitalist mode of production to seeing the latter as having abolished the working class itself.[2]

Unfortunately, the search for answers to the question of the *social* determinations of revolutionary subjectivity in the work of contemporary Marxist scholars – where one would expect to find them – does not look very promising either. Certainly, there have been plenty of interesting developments within the Marxist tradition in recent times; in particular, among those working within a broadly understood 'form analysis' approach.[3] Thus, since the 1980s there have been important contributions to the investigation of the more general economic form determinations of capitalist social relations,[4] the state form,[5] the legal form,[6] and, more recently, a renewed interest in Marx's dialectical method and its connection to Hegel's.[7] A

large number of novel detailed commentaries on (and introductions to) Marx's *Capital* have appeared as well.[8]

However, not many works have actually put the problematic of revolutionary subjectivity at the centre of the critique of political economy. I do not want to imply that scientific reflection on the determinations of revolutionary subjectivity has been *completely* absent from recent Marxist theorising (although it must be said that many of the contributions to the resurgence of value form theory since the late 1970s and early 1980s, and certainly most of the discussions of the dialectical method, did fail to establish a firm link between revolutionary theory and the concrete political action of the working class).[9] But in the few cases where that question has been explicitly addressed, emancipatory subjectivity has usually been grasped, as Postone rightly notes, as *transcendentally* or *ontologically* rooted.[10] This means, in a nutshell, that the ground for emancipatory subjectivity is seen as standing *outside* the alienated forms of social mediation through which the life process of humanity asserts itself. For instance, the substance of revolutionary subjectivity is seen as residing in a generic material content – the 'constituting power of human productive practice' – which, in its most refined versions, constitutes the negated presupposition of capitalist forms of social mediation.[11] That is, the content of revolutionary subjectivity is not grasped as the 'unity of many determinations', but remains simple and *unmediated*, mediation pertaining at best only to *non-revolutionary* forms of working-class subjectivity. In the same vein, the exposition of the determinations of revolutionary subjectivity is not the *synthetic* result of the scientific dialectical unfolding of the movement of the social forms of capitalist society, but is represented as the product of the *analytic* reduction of those social forms to the postulated generic material content.[12] The scientific critique of capital thereby comes down to the invocation of the powers of an unmediated human practice in the form of a (Kantian) moral imperative.[13]

[9] As commented by Mohun, regarding value theory, in a collection of essays from those debates (1994a, p. 4).

[10] Postone 1996, p. 38.

[11] Cf. Bonefeld 1995.

[12] This point was insightfully hinted at in the 1970s by Giacomo Marramao in his critical appraisal of the polemic between the more subjectivist positions of Korsch and the Dutch Left Communists (Pannekoek, Gorter) and the defenders of the theory of capitalist breakdown (Mattick, Grossmann) (Marramao 1975–6, pp. 152–5; 1982, pp. 139–43). As Marramao states against the 'spiritualisation' of revolutionary consciousness by Pannekoek: 'Thus, the genesis of class consciousness is not *explained* in terms of the process of production and reproduction, and from within the objectivity of social relations, but is *presupposed* as

Eventually, the logic of this approach ends up taking the conscious reflection on the determinations of revolutionary subjectivity away from *social theory* (the critique of political economy) and into the realm of *philosophy*. Thus, in his recent investigation of revolutionary subjectivity, Holloway abandoned the approach of his earlier work on the economic and political forms of capitalist social relations of production, and conceptualises revolutionary theory through a blend of an Adornian philosophical critique of 'identity' and a Blochian philosophy of hope.[14] In another, widely debated strand of work, Hardt and Negri, even if at least offering some insights into the *social* determinations of working-class subjectivity (e.g. through their theory of 'immaterial labour'), ultimately ground its revolutionary form through a recourse to a different philosophical combination: an *ontology* of the 'productivity of desiring machines' inspired by the poststructuralism of Deleuze and Guattari, and a Spinozan *political philosophy* of the 'multitude'.[15]

The key to the overcoming of the limitations of all these approaches has been correctly identified by Postone in his own recent attempt to reconstruct the Marxian critique of political economy: emancipatory subjectivity must be *socially* grounded.[16] Hence, it is a question pertaining to dialectical *social theory* – the critique of political economy – and not to philosophy. More concretely, this means grasping emancipatory subjectivity as *immanent* in the very unfolding of the reified forms of social mediation of capitalist society. Hence, Postone rightly argues, the question that critical social theory faces is to discover emancipatory consciousness as socially constituted by the alienated *historical* dynamic of capital itself.[17] The problem with his approach is that in his idiosyncratic reconstruction of the Marxian critique of political economy, that historical dynamic actually *denies* the working class (*qua* working class) the determination of material bearer of revolutionary subjectivity.

---

a result of an irreducible autonomy that at a certain point of development, makes the qualitative jump which breaks the quantitative uniformity of the empirical world' (Marramao 1975–6, p. 155). Marramao's additional point, namely, that the elements for a dialectical alternative to this subjectivism can be found in the work of Grossmann, is, however, less persuasive.

[13] As pointed out by Neary 2004.

[14] Holloway 2002b, and 2010.

[15] Hardt and Negri 2000, 2004, and 2009.

[16] Postone 1996, p. 38.

[17] Postone 1996, p. 38.

This book takes up the challenge posed by Postone and aims at the development of a materialist inquiry into the social and historical determinations of revolutionary subjectivity. It also does this through a *critical reconstruction of the Marxian critique of political economy*. One, however, that yields an opposite result to that of Postone, namely, that the outcome of the historical unfolding of the dialectic of the objectified form of social mediation turned into the very alienated subject of social life (i.e. capital) is to determine, as its own *immanent* determination, the constitution of the (self-abolishing) working class as a revolutionary subject.

A crucial element in this intellectual endeavour is the recovery of the old Marxian insight, contained in the oft-quoted passage from the Postface to the second edition of *Capital*, into the intrinsic connection between the specifically dialectical form of social science and its revolutionary content.[18]

> In its mystified form, the dialectic became the fashion in Germany, because it seemed to transfigure and glorify what exists. In its rational form it is a scandal and an abomination to the bourgeoisie and its doctrinaire spokesmen, because it includes in its positive understanding of what exists a simultaneous recognition of its negation, its inevitable destruction; because it regards every historically developed form as being in a fluid state, in motion, and therefore grasps its transient aspect as well; and because it does not let itself be impressed by anything, being in its very essence critical and revolutionary.[19]

In this sense, it could be said that this book represents a *methodologically minded* development of the critique of political economy. More precisely, the book argues that the latter is but the scientific self-consciousness of the working class about its own social determinations as an alienated yet revolutionary subject. Because of this determination, itself the product of its dialectical form, social science becomes determined as *practical criticism*.

This general methodological approach to the critique of political economy adopted in this book is primarily inspired by the work of the Argentine independent scholar Juan Iñigo Carrera, to whom I feel immensely in debt for many of the ideas developed here.[20] As I hope to demonstrate throughout the course of the argument, this approach is highly original and provides a rigorous and powerful answer to many of the scientific questions that Marx scholars (especially those associated with those currents of critical Marxism that have tried to break with the Marxist-Leninist orthodoxy) have been debating at least over the last 30 years. Unfortunately, very few of Iñigo Carrera's works have been published in English.[21] Coupled with the fact that his research has been carried out independently, i.e. outside the formal structures of academia, Iñigo Carrera's work has remained largely unknown within English-speaking Marx scholarship. A first aim of this book, then, is to introduce this particular approach to the critique of political economy to the wider English-speaking readership. Furthermore, this book also intends to show that this approach provides not only a powerful tool for the contemporary further development of the critique of political economy, but also a very fruitful way of uncovering the methodological thread that gives unity to Marx's overall intellectual development. In particular, I have utilised the clues found in Iñigo Carrera's writings to develop a close reading of Marx's major work, namely, *Capital*.[22] Through this reading, I hope to prove my point about the revolutionary nature and contemporary relevance of the Marxian critique of political economy.

---

[18] A point forcefully made after Marx's death fundamentally by Lukács in *History and Class Consciousness* (1971).

[20] See Iñigo Carrera 1992 and 2008.

Structure of the Book

To develop the argument, the book is structured into two parts. A critical reading of Marx's early writings from the perspective of his later works is carried out in the three chapters comprising the first part of the book. The reading attempts to find in both the insights and limitations of the young Marx clues towards the direction that his scientific development would take and which would culminate in the intellectual and political necessity of writing *Capital*. This critical engagement with Marx's early texts is not carried out through an exhaustive chronological assessment of each of those works, a task which in itself would require a whole book and which, moreover, would presumably reveal plenty of repetitions in terms of the scientific achievements contained in each text (e.g. the materiality of human productive subjectivity in both the *Paris Manuscripts* and *The German Ideology*). Rather, the book selects and concentrates on three key moments in Marx's early intellectual development which, I think, demonstrate with greater force both the achievements and limitations of the early writings in terms of the revolution in the mode of scientific knowledge that Marx was undertaking, and that would eventually crystallise in the writing of *Capital* as the most developed form of the critique of political economy, that is, of the dialectical critique of the capital form.

---

[21] Only very recently, a couple of articles on method (Iñigo Carrera 2013 and 2014) and some of his empirical work on the specificity of capital accumulation in Argentina (Iñigo Carrera 2006) have come to light in the English-speaking world. Many of his other articles in Spanish are available now on his website: http://www.cicpint.org/.

[22] At the time of finishing the first draft of this manuscript, there was no published detailed commentary on Marx's *Capital* by Iñigo Carrera. A commentary on the first chapter is now available. See Iñigo Carrera 2007. I have nonetheless benefited greatly from illuminating discussions over the past 17 years, throughout which I have collaborated closely with him. In addition, recordings of his course on *Capital* (in Spanish) have recently been uploaded on his website.

The first two chapters deal with two different aspects of the 1844 *Paris Manuscripts*. Chapter 1 firstly outlines some of the crucial breakthroughs contained in that text. In the first place, it points to this work as involving Marx's first *materialist* comprehension of the revolutionary subjectivity of the proletariat. And this meant the overcoming of the *philosophical* standpoint from which he had previously grasped the emancipatory mission of the working class. The chapter further argues that this transcendence of the philosophical representation of proletarian subjectivity actually springs from another fundamental achievement found in the *Paris Manuscripts*, namely, the discovery that the key to the comprehension of any historical movement lay in its referral to the development of the *materiality* of human *productive* individuality. On the other hand, I also argue in Chapter 1 that Marx's elaboration of all these theoretical breakthroughs eventually clashed with an insurmountable barrier: the *methodological insufficiencies* underlying this first attempt at a critique of political economy. I show that Marx's reliance on a Feuerbach-inspired transformative criticism, although serving him analytically to uncover alienated labour as the hidden foundation of 'economic categories', eventually leaves him unarmed to comprehend the historical dynamic of alienated labour in the qualitative specificity of its concrete forms. He thus resorts to an *extrinsic* application of a *general* dialectic formally borrowed from Hegel's *Phenomenology of Spirit*. The unfolding of the concrete social determinations of revolutionary subjectivity could not but remain outside the reach of this early critique of political economy.

Chapter 2 undertakes closer scrutiny of two fundamental claims made in the first chapter. First, that Marx's adoption of a materialist perspective was tantamount to the transcendence of philosophy. In the second place, I argue that, especially through the confrontation with Hegel's philosophy in the third manuscript, Marx starts to show self-awareness of the inadequacy of the transformative method inherited from Feuerbach as the revolutionary form of proletarian science. Moreover, I argue that both questions are intrinsically connected. In order to do this, and unlike most commentaries, the chapter focuses not on Marx's critique of Hegel's *Phenomenology*, but rather that of the *Science of Logic*. It is argued that it is especially with the latter critique that Marx became aware of the essential character of philosophy as uncritical alienated thought and, hence, of the need to overcome philosophy *tout court*. At the same time, the chapter advances the proposition that the very same confrontation with Hegel's *Science of Logic* was crucial for Marx's first steps in the critical appropriation of the 'rational kernel' to be found in the Hegelian dialectic, namely, the discovery of the revolutionary essence of the 'reproduction of the concrete by means of thought' – i.e. dialectical cognition – as the necessary *method* of science determined as practical criticism. Whatever the role played in the *Paris Manuscripts* through its materialist inversion as the dialectic of human labour, the self-development of Spirit through alienation and its overcoming is not where that rational kernel resides. Rather, the chapter argues, already at that early stage Marx was coming to terms with the fundamental distinction between what Hegel called the 'understanding', with its characteristic externality between the ideal necessity of thought and the inner life of the object of scientific cognition, and what he called 'speculative thought', as the form of scientific cognition with the power to follow in thought the movement of negativity immanent in real forms. However, Marx did not uncritically appropriate that insight, but instead turned that distinction against Hegel himself.

Some of the essential ramifications of this early recovery of the revolutionary power of the dialectical method are explored in Chapter 3, mainly by means of a reconstruction of Marx's critique of Proudhon. The latter, I think, constitutes another key moment in Marx's intellectual development that condenses the theoretico-methodological breakthroughs he achieved during the 1840s. The first methodological aspect that crops up in Marx's critique of Proudhon is the critical distinction between dialectical *logic* and dialectical *method*. The former is what results when the dialectic is conceived of as a general formalistic methodology to be taken ready-made from Hegel's *Science of Logic* and then applied to whatever particular content we face; in the case of Proudhon, to the 'material' questions of political economy. By contrast, the dialectical method does not consist in the application of the general necessity of logic – however 'dialectical' in form – to particular objects, but simply follows in thought the *specific* necessity immanent in social forms themselves. Hence the significance of the *Poverty of Philosophy*: it contains Marx's first positive attempt to reproduce in thought the real movement of capitalist economic forms. Moreover, I try to show that this critique of Proudhon entails much more than an abstractly methodological interest; rather, the text reveals that at stake is the knowledge of the social determinations of the political action of the working class. In brief, the text makes evident the *political* nature of the dialectical critique of political economy determined as the conscious organisation of the practical critique of the capital form.

And yet the rudimentary and germinal state of Marx's critique of political economy at that stage limited the scientific comprehension of the social determinations of revolutionary subjectivity to an equally underdeveloped stage. The political task that Marx faced thereby became clear to him: to put all these theoretico-methodological insights gained in the 1840s concretely into motion by giving the dialectical critique of political economy its fully developed shape. This, the first part of the book partially concludes, is what the writing of *Capital* was all about.

The second part of the book aims at substantiating this last point through a methodologically minded critical reading of Volume 1 of *Capital* and the *Grundrisse*. Chapters 4 and 5 develop a very close reading of the first chapter of *Capital* in order to show how only through a sound comprehension of the dialectical method, as broadly reconstructed in the first part of the book, can the implications of Marx's presentation of the determinations of the commodity form be uncovered in all their plenitude. Particular attention is given to Marx's investigation of the commodity form as entailing both the most general form of *objectivity* and *subjectivity* of the capitalist mode of production, an issue that is spelled out in Chapter 5. On the other hand, Chapter 6 also problematises the relation between the critique of these more abstract forms of alienated social life and the uncovering of the concrete determinations of emancipatory subjectivity. The argument put forward is that the former constitutes only a first step of a laborious journey involving the reproduction in thought of the further mediations underlying the latter. Only by going through that development can the critique of political economy become determined as the self-consciousness of the social necessity of revolutionary action.

This point is reinforced in Chapter 7 through a reconstruction of the precise form in which Marx introduces the class struggle in his dialectical presentation and a discussion of various implications that follow from it. In contradistinction to many contemporary readings that tend to *ontologise* the class struggle, thereby turning it into the most general *content* of the movement of social life in its capitalist form, the chapter argues that it is a necessary *form* in which the valorisation of capital realises its determinations. The reason for this does not lie in the formalistic methodological principles of structuralism.[23] Rather, it is an expression of the concrete development of the historically specific alienation inherent in the commodity form; in the form of the *total social capital*, the materialised social relation between private and independent individuals *becomes determined as the concrete subject of the movement of modern society*. This does not imply the denial of the transformative powers of human practice personified by workers. But it does imply that whatever transformative powers the political action of workers might have – *both* capital-reproducing *and* capital-transcending political action – must be an immanent determination begotten by the alienated movement of capital as subject and not external to it. And in its *simplest* determination (i.e. as an expression of the *formal subsumption* of labour to capital), the class struggle only exists as a necessary form of capital's reproduction, but not of its transcendence.

---

[23] As alleges Bonefeld 2014.

As explored in Chapter 8, the socio-historical genesis of the emancipatory subject can be found in the transformations in the *materiality* of social life brought about by the *real subsumption* of humanity to capital. As Marx shows in *Capital* and the *Grundrisse*, through the constant revolution in the material conditions of social labour, capital progressively transforms the subjectivity of the workers according to a determinate tendency: they eventually become *universal labourers*, that is, organs of a collective subject capable of consciously ruling their life process by virtue of their power scientifically to organise the production process of any system of machinery and, therefore, any form of social co-operation. This mutation of their *productive subjectivity* is the necessary prelude to the constitution of the labourers as truly social individuals through their self-abolition as wage workers and the construction of the free association of individuals. This, I argue, is the inner material *content* of social life which is expressed in the *form* of the political revolutionary subjectivity of workers.

By way of a conclusion, Chapter 9 provides a further examination of the determinations of revolutionary subjectivity beyond those explicitly developed by Marx. By drawing together and elaborating on many themes only tangentially touched upon in the previous chapters, the concluding remarks of the book explore the further qualities of the emancipatory subject: the alienated nature of its transformative action; its inner material determination as productive subject; the specific scientific form of revolutionary consciousness (i.e. dialectics); the connection between the revolutionary abolition of the capital form and the 'conquest of state power'; and, finally, the necessity for its action to be consciously self-organised.

PART 1

Marx's Early Critique of Political Economy: The Discovery of the Revolutionary Subject and the Development of Science as Practical Criticism

∴

CHAPTER 1

The Dialectic of Alienated Labour and the Determinations of Revolutionary Subjectivity in the *Paris Manuscripts*

Introduction

There was a debate among scholars in the 1960s and 1970s over the way in which Marx came to embrace the idea – explicitly appearing for the first time in the *Introduction to the Contribution to the Critique of Hegel's Philosophy of Right* – of the proletariat as the revolutionary subject of the abolition of the capitalist mode of production. Was it through 'empirical' contact with real proletarians? Tucker states it was not, and claims that it was through the reading of socialist and communist literature of the time.[1] Avineri, for his part, argues that it was through the critique of Hegel and his notion of a universal class.[2] Finally, McLellan thinks that it was through his immersion in a radical-socialist political and intellectual environment as he moved from Germany to Paris.[3]

Now, as Perkins rightly notes, what matters is not the biographical question of how Marx came to discover the proletariat, but the *meaning* of that discovery.[4] In this sense, regardless of the precise form in which Marx came to discover the proletariat as a revolutionary force, the crucial point to highlight is that, until 1844, the proletariat was for Marx a *philosophical category*. More concretely, it was the mediating category through which he tried to make philosophy descend from the heavenly realm of abstract thought to the real social life of concrete human beings.[5]

---

[1] Tucker 1961.

[2] Avineri 1993, pp. 52–64.

[3] McLellan 1973, p. 97.

[4] Perkins 1993, p. 33. Apart from the works by Tucker, Avineri and McLellan cited above, classic but still good sources on the details of Marx's intellectual evolution and biography can be found in Rubel 1975 and 1980 and Oakely 1983, and 1984–5. Musto 2010a provides a more recent examination of Marx's intellectual biography up to the *Grundrisse*, incorporating the latest advances of philological research based on the MEGA project. For a commentary on the later, see Musto 2010b.

[5] Perkins 1993.

© KONINKLIJKE BRILL NV, LEIDEN, 2016 | DOI: 10.1163/9789004306608_003

Thus, even if he were attempting to transcend what he saw as the abstract character of idealist philosophy as present in both Hegel and the Young Hegelians, I think that Marx's intellectual development before the *Paris Manuscripts* was carried out within the boundaries of philosophical discourse. In particular, he was attempting to solve the whole theory-practice problematic as it appeared when seen through philosophical lenses. And this meant that, thus conceived, his endeavour was doomed to failure from the very outset. As I shall argue in the following chapter, in the *Paris Manuscripts* Marx would come to discover that it is in the very essence of philosophy (however 'materialist' or 'dialectical' in form) to remain trapped within abstract thought and, therefore, to be indifferent to the real movement of human practice. Within the limits of philosophical thought, no real mediation is possible between theory and practice, only the appearance of it. Or, seen from another angle, within philosophy the relation between theory and practice cannot but become inverted. Instead of seeing revolutionary science ('theory') as the necessary concrete form through which the transformative action of the proletariat ('practice') is consciously organised, the latter appears as the necessary form through which the universal claims of philosophy are realised. Revolution thus becomes a logical necessity of philosophy and consists in making the world become 'philosophical'.[6]

The perspective of the *Paris Manuscripts* is very different. In this text Marx's starting point is no longer the universal claims of philosophy. As he states when opposing political economy's recourse to a mythical primitive society of simple commodity producers: 'we shall start out from a *present-day* economic fact'.[7] Marx attempted to analyse this concrete economic form in its historical specificity and existing reality and, *from this point of departure*, he *then* both made sense of previous history and discovered the hidden transitions to the supersession of modern capitalist society. Hence, communism ceased to be a philosophical *ideal* in any meaningful sense of the word, notwithstanding the mediations with the real introduced, and became 'a *real* phase, necessary for the next period of historical development, in the emancipation and recovery of mankind'.[8] As Marx put it in an oft-quoted passage from *The German Ideology*:

> Communism is for us not a *state of affairs* which is to be established, an *ideal* to which reality [will] have to adjust itself. We call communism the

[8] Marx 1992b, p. 358.

> *real* movement which abolishes the present state of things. The conditions of this movement result from the premises now in existence.[9]

The quotation cannot be clearer. Although there is a formal similarity between Marx's approach to the problem of social transformation before and after August 1844 (in terms of the finding of the future immanent in the present), there is also a subtle difference expressed in the passage from philosophy to materialist science; one, however, which cannot be neglected if we want to grasp the innovations in Marx's thought to be found in the *Paris Manuscripts*.[10]

The second central aspect of the *Paris Manuscripts* is a direct result of Marx's first attempt at the critical investigation of the specific nature of modern society through the critique of Hegel's *Philosophy of Right*, i.e. through an analysis of bourgeois political forms. As Marx himself tells us in the short intellectual 'autobiography' found in the *Preface to the Contribution to the Critique of Political Economy*, the main conclusion he reached was that the key to the comprehension of the specific nature of capitalist society was not to be found in the critique of the doctrine of the state, but that the critique of modern society had to start with the critique of political economy in order to, then, continue into a critique of the state.[11] This was the science that was able to penetrate the 'internal physiology' of the modern world to be found in 'civil society' and, more precisely, in 'private property'.[12]

In light of this conclusion, in the *1844 Manuscripts* Marx turns his attention to the way in which human life is materially reproduced as the key to the understanding of society and its historical development. As Arthur points out,

---

[9] Marx and Engels 1976a, p. 49.

[10] For a philological discussion of Marx's manuscripts and notebooks of 1844, see Musto 2009. On the *meaning* of Marx's intellectual development leading to the writing of the *Paris Manuscripts*, see Murray 1988 and Teeple 1984. The latter, in particular, raises the point of the often neglected importance in the development of Marx's ideas of his doctoral dissertation. Löwy's important book on the theory of revolution in the young Marx is also quite illuminating for the early stages of Marx's intellectual evolution (Löwy 2003). It is also especially relevant for the argument developed here insofar as Löwy specifically focuses on the question of emancipatory subjectivity, albeit from a different theoretical perspective. More recently, Leopold has critically re-examined the early Marx's relationship with prior German philosophy, particularly with Bauer's and Feuerbach's thought, covering the writings from the period stretching from March 1843 to September 1845 (Leopold 2007).

[11] Marx 1992d, pp. 425–6.

[12] Teeple 1984, p. 201.

> [F]or the first time he attributes fundamental ontological significance to *productive activity*. Through material production humanity comes to be what it is … material production is the '*mediation*' in which the unity of man with nature is established.[13]

Marx therefore placed, for the first time, the material determinations of human society in the centre of his inquiry. The critical standpoint originally developed in the *Introduction to the Contribution to the Critique of Hegel's Philosophy of Right* thereby acquired a more concrete meaning. In that text, Marx stated that the radicality of the critique was to be measured by the extent to which it 'grasped things' as having their roots in human beings themselves.[14] In the *Paris Manuscripts*, this general statement about tracing all socio-historical forms to the practical activity of individuals became more specific. The key to the comprehension of any historical movement lay in its referral to the development of human *productive* subjectivity. That is, in tracing social forms to what he discovered to be specifically human about the human being.

Simply as such this emphasis on the material determinations of society is certainly not peculiar to Marx. As Clarke notes, this is a feature that one can find in Classical Political Economy and that it inherited from the Scottish Enlightenment.[15] Yet in opposition to the ahistorical naturalism of, for instance, Adam Smith's theory of the co-evolution of modes of subsistence, class relations and forms of property, Marx's originality lay in unearthing the historical specificity of the social forms in which human productive subjectivity developed or the historicity of what he would later call the social relations of production.[16] Clearly, at this stage Marx did not posit the question explicitly in these latter terms. However, as Colletti rightly points out, many of the elements constituting the mature critique are, certainly in an underdeveloped and abstract form, in this early text.[17] When dealing with the question of the historicity of social forms, I am already entering into the discussion of another central aspect of the *Paris Manuscripts*. For here he discovered the specificity of bourgeois relations of production in *alienated labour*.

The aim of this chapter is thus to critically investigate the breakthroughs achieved by Marx in that early text from 1844. The said discovery of the historical specificity of alienated labour and, what is the flipside of this, of the economic content of the communist transformation of human life, definitely constitutes one of the fundamental scientific achievements to be found in the *Manuscripts*; one, moreover, which would lay the foundations for Marx's subsequent intellectual development. In this sense, one could argue that the *Paris Manuscripts* constitute a necessary *first* step in the production of Marx's revolution in the *mode of scientific knowledge* that the radical transformation of the world demands. On the other hand, we shall also see that the *methodological insufficiencies* of that text did not allow Marx to take that revolutionary transformation of scientific knowledge into *practical criticism* to completion. And yet, as argued in the course of this book, it was precisely the self-awareness of those limitations that gave Marx the key to the path that his scientific revolution needed to undertake.

Transformative Method and the Discovery of Alienated Labour

The first issue that emerges when engaging with Marx's analysis of alienated labour in the *Paris Manuscripts* is the risk of becoming bogged down in what by now might seem like the tedious and somewhat scholastic question of the relation between Marx's earlier works and *Capital*. This story is quite well-known. In opposition to structuralist readings of Marx, which postulate a rupture between a Hegelian-idealist young Marx and a materialist-scientific mature Marx,[18] 'heterodox' Marxist perspectives tend to have as their defining characteristic the view that there is continuity running through the whole of Marx's work. According to the latter, this unity within Marx's intellectual enterprise is determined by his discovery of alienation as the fundamental aspect of his critique of capitalist society. In this sense, this tradition of unorthodox Marxism stresses the importance of the Hegelian influence on Marx's thought for understanding the critical nature of his work. Hence, these authors tend to adopt as a strategy the return to both Hegel and the young Marx, in order to recover the critical force that resides in *Capital*.

Writing in the twenty-first century, it is more than fair to say that this debate has been settled both from a theoretical and textual point of view.[19] The existence of an inner unity underlying the different phases of Marx's intellectual project is now part of the 'ABC of Marxism'. Yet this consensus still begs two related questions. First, the precise meaning of 'alienated labour' in Marx's thought. Second, the question of the difference through which that unity of Marx's thought asserts itself.[20] The clarification of these questions is crucial for our purpose of tracing Marx's discovery of the determinations of the revolutionary subjectivity of the proletariat. Or, to be more exact, the former task is synonymous with the latter. An emphasis on an abstract identity between 'the young Marx' and 'the mature Marx' leads to an obliteration of the differences that it is possible to find in the concrete development of Marx's work and, therefore, to an external imposition of the young Marx's analysis of alienation onto *Capital*.[21] Moreover, inasmuch as those differences imply a deepening of Marx's investigations of the social determinations of alienated labour into an analysis of the particular forms that this alienation takes, of their movement – i.e. their inner connection – and of their contradictory historical development into their own annihilation, those readings risk depriving the critique of political economy of its concrete revolutionary power. The key to avoiding these shortcomings consists, as Levin suggests,[22] in inverting the reading strategy of most defenders of the 'continuity thesis'. That is, instead of trying to demonstrate the presence in *Capital* of the themes developed in the *Paris Manuscripts*,[23] it is necessary to assess the early texts in light of the mature form in which Marx presented those very same insights. Only in this way is it possible to grasp both the merits and the *limitations* of Marx's early critique of political economy.

---

[18] The *locus classicus* of this position within non-Soviet Marxism is Althusser 1969. The most comprehensive critical assessment of Althusser's work can still be found in an early work by Clarke 1980.

[19] Marcus 1982, p. 140.

In this regard, I think that the very form of Marx's investigation (i.e. the method utilised in this first critical encounter with political economy) constitutes the main limitation to be found in the *Manuscripts*. Marx's critical appropriation of the critical power of the dialectical method had not fully developed at this stage and he was still under the influence of Feuerbach's transformative criticism.[24] In the *Manuscripts*, Marx attempted to do with political economy what he had previously done with Hegel's *Philosophy of Right* (and what Feuerbach had done with religion). That is, whereas in 1843 he applied the transformative method to the theorists of the political forms of bourgeois society, in 1844 he applied it to the scientific representations of economic forms.

---

[20] Marcus 1982, p. 141. Clarke develops a useful critical assessment of the shortcomings of both orthodox and heterodox readings of Marx's analysis of alienated labour in the *Paris Manuscripts* (Clarke 1991a, pp. 70–8). A more recent concise overview and assessment of those debates on Marx's concept of alienation can be found in Musto 2010c. In the last 30 years, and with the controversy over the unity in Marx's thought broadly settled, the interest of Marxists has moved away from his early discussion of alienated labour into his 'mature' notion of fetishism in *Capital*. See, however, Sayer 2011.

[21] See, for instance, Elliot 1979; Walton 1972.

[22] Levin 1997, pp. 63–4.

[23] Cf. Avineri 1993.

[24] See O'Malley 1970, pp. xxviii–xxxii; Avineri 1993, p. 10; Breckman 1999. Colletti, however,

Basically, Marx's transformative method involves four interrelated moments. First, the denunciation of the hypostasis whereby the forms of social objectivity are presented by theory as self-subsistent and actually determining the life of the human individual, who becomes determined as the predicate of those social institutions turned into the subjects of social life. Secondly, the refutation of the claims of those theories by referring all forms of autonomised social objectivity back to their origin in the practical life of the human being, that is, understanding the former as forms of alienated objectification of specifically human attributes, capacities and relations. Thirdly, the exposure of the contradictions that arise in theory for its naturalisation of this inversion between subject and predicate. Finally, the recognition that those theories are not simply false in the sense of offering an inaccurate characterisation of social life, but that both their conceptual inversion of subject and predicate and their internal contradictions are uncritical expressions of real inversions and contradictions existing in society.

What is important to note is that, in this approach, the motion of social forms themselves is not engaged with. Transformative criticism of capitalist society develops through the (textual) analysis of the theories of those authors who, within the limits of their bourgeois horizon, took the scientific comprehension of the former to its highest possible development. But there is no independent study of the movement of social forms themselves. Hence, the object under critique (capital or alienated labour) can only be grasped as an undifferentiated totality whose historical 'laws of motion' are not subject to investigation. In fact, as Markus suggests,[25] at times Marx gives the impression that the whole enterprise of offering an alternative critical presentation of the concrete forms

---

warns the reader of his edition of Marx's *Early Writings* that the influence of Feuerbach should not be overstated, since the theme of the inversion between subject and predicate 'is in fact one of the most profound and ancient themes in philosophical history' (1992, pp. 23–4). Still, Colletti himself concedes that it was a contribution of Feuerbach to develop that theme in the specific context of the critique of Hegel. Moreover, what is relevant for my argument is not the intellectual lineage of the method of transformative criticism, but the fact that Marx resorted to it. Another author who casts doubt over the alleged influence of Feuerbach is Teeple (1984, pp. 47–8). But, again, he does not deny that the method of inversion of subject and predicate plays a part in Marx's critique of Hegel.

[25] Marcus 1980, p. 82; and 1982, pp. 141–2.

of motion through which alienated social life develops is doomed from its very beginning. Especially in the first pages of the *Manuscripts*, the tone of his presentation seems to equate such a project with a complicit attitude towards these alienated forms of social life. Yet we cannot generalise this to the whole of the *Manuscripts*. As we will see, it is one of Marx's scientific results in this text to reach the conclusion that not only does such an alternative account not involve an uncritical stance towards capital, but it is also the necessary form to discover the ways in which to transcend it. Without this mediation, the scientific critique of capital remains too general and abstract and, hence, impotent to develop into conscious revolutionary action.

Hence the crucial importance of the question of the methodological limitations of the *Manuscripts*, which impinge on the rest of the exposition and, therefore, on Marx's investigation of the social determinations of the revolutionary subjectivity of the proletariat. In fact, Marx's awareness of this problem acted as a trigger for the direction that his subsequent research would take: the self-clarification regarding the adequate form of critical scientific knowledge and the positive (dialectical) exposition of the determinations of the totality of capitalist social forms. Retrospectively, one can say, paraphrasing the mature Marx, that his utilisation of Feuerbachian transformative criticism proved helpful in order to 'discover by analysis the earthly kernel of political economy' (alienated labour). However, this method proved impotent to 'develop from the actual, given relations of life the forms in which these have been apotheosized'.[26] In order to substantiate this claim, let us move to the concrete examination of Marx's discussion of the determinations of alienated labour.

As already noted, Marx does not take as his starting point the economic forms of capitalist society themselves, but instead engages with the *categories and* (*external*) *relations* through which political economy represents them.[27] Thus the first part of the first manuscript is devoted to an unoriginal exposition of the theories of political economy in their own terms, showing the antinomies that arise according to the very same 'laws of movement of private property'.[28] On the one hand, political economy finds in labour the 'subjective essence of private property', which is thus turned into the principle of this specifically modern science.[29] On the other, the autonomous movement of private property it postulates results in the degradation and misery of the worker, the material bearer of that principle. Even when the wealth of society is increasing, the poverty of the worker does so too, in relative if not absolute terms. Moreover, every progress in the productivity of labour is also turned against the worker: its outcome is not the creation of disposable time for her/his 'spiritual' development, but an expansion of the amount of manual work she/he performs. The introduction of machinery, through which this increase of productivity takes place, also has the effect of deskilling the capacities of the labourer.[30] In brief, political economy, as 'private property become conscious for itself … modern industry as self', postulates at the same time the affirmation and denial of the human being.[31] As Marx himself tells us at the beginning of the section on alienated labour, it is by advancing through the concepts of political economy taken as given that he arrives at this contradiction:

---

[26] Marx 1976g, p. 494.

[27] Iñigo Carrera 2013, pp. 44–5.

[28] Marcus 1980, p. 81.

[29] Marx 1992a, p. 341.

> We have started out from the premises of political economy. We accepted its language and its laws … From political economy itself, using its own words, we have shown that the worker sinks to the level of a commodity, and moreover the most wretched commodity of all; that the misery of the worker is in inverse proportion to the power and volume of his production.[32]

Since political economy 'proceeds from the fact of private property', it just unconsciously expresses this contradiction without actually 'explaining it'.[33] Through the path consisting in the development of the concepts of political economy, Marx was able to discover the foundation of this contradiction in the character of productive activity under the specific capitalist form, namely, in *alienated labour*. The objectivity in which the subjective powers of the worker are realised is turned into an alien power that dominates the producer herself/himself. This, says Marx, is the reason behind the autonomous movement of private property that results in the mutilation of the worker's subjectivity:

> All these consequences contained in this characteristic, that the worker is related to the *product of his labour* as to an *alien* object … The externalization [*Entäusserung*] of the worker in his product means not only that his labour becomes an object, an *external* existence, but that it exists *out-*

[33] Ibid.

> *side him*, independently of him and alien to him, and begins to confront him as an autonomous power; that the life which he has bestowed on the object confronts him as hostile and alien.[34]

Two important remarks are in order in light of the previous quote. In the first place, as Clarke remarks, it is clear that this alienation of the worker's productive powers as attributes of the product of labour does not refer either to an ideological or psychological problem of false consciousness on the part of the labourer,[35] or to her/his subjective experience of indifference towards the work she/he is doing[36] – although this is likely to be the case as a concrete manifestation of alienated labour. Nor does it refer to the fact that the labourer has to subordinate the exercise of her/his consciousness and will in the production process to the direct authority of the capitalist who, in turn, expropriates the product of the former's labour.[37] The alienation of the productive activity of the labourer refers to *a real inversion between subject and object*, where the latter dominates the former. In order to make this point clear, it is important to note that, for Marx, this alienation also reaches the capitalist. The alienation inherent in the capitalist social form of human life involves, as I shall comment on below, the realisation of the human species-being itself – i.e. productive activity – in the form of an alien and impersonal power, the power of a thing. And this includes the non-labourer too. This is why Marx states at the end of the first manuscript that 'everything which appears for the worker as an *activity of alienation, of estrangement*, appears for the non-worker *as a state of alienation, of estrangement*'.[38] As much as the labourer, the capitalist also actualises her/his human species-being. However, she/he does so only in the form of the direct coercive control over the productive activity of the labourer in the alienated name of her/his capital. Therefore, her/his conscious life activity does not participate *directly* in the *active* transformation of the objective world. Nonetheless, in this process the capitalist does not act freely. She/he only acts *as the immediate personification of the human powers incarnated as attributes of the product of labour which dominates the producer*. Hence, she/he is alienated too, but this alienation is expressed in the capitalist as a *state* instead of as an *activity*. In other words, the realisation of the activity of the labourer under the direct 'coercion and yoke of another man'[39] is a concrete form of an essentially inverted mode of existence of humanity's life activity. In the words of Marx:

---

[34] Marx 1992a, p. 324.

[35] Clarke 1991a, p. 75.

[36] As in De Angelis's reading (1995).

[37] Maguire 1972, p. 67; Mandel 1971.

[38] Marx 1992b, p. 334.

> So through estranged labour man not only produces his relationship to the object and to the act of production as alien and hostile powers; he also produces the relationship in which other men stand to his production and product, and the relationship in which he stands to these other men.[40]

And this leads to the second remark: now there can be no doubt that for Marx *alienated labour* (*understood as this real inversion between the producer and the product*) *is the defining characteristic of the specific form of labour under capitalist social relations of production*.[41] This becomes evident in the section on rent of the first manuscript, with the analysis of feudal landed property and its necessary transition into capitalist private property. There Marx contrasts the command over the human productive power of the serf as a personal attribute of the feudal lord (and hence as the *direct* or *personal* political domination of the former by the latter), with the command over the human capacities of the free worker as an *impersonal*, *objective* attribute of the product of labour in the form of capital, which, as stated above, dominates both the producer and the non-producer:

> It is inevitable that this appearance should be abolished and that landed property, which is the root of private property, should be drawn entirely into the orbit of private property and become a commodity; that the rule of the property owner should appear as the naked rule of private property, of capital, divested of all political tincture … Finally, it is inevitable under these conditions of competition that landed property, in the form of capital, should manifest its domination both over the working class and over the property owners themselves, inasmuch as the laws of the movement of private property are either ruining them or raising them. In this way the medieval saying *nulle terre sans seigneur* gives way to the modern saying *l'argent n'a pas de maître*, which is an expression of the complete domination of dead matter over men.[42]

---

[39] Marx 1992b, p. 331.

[40] Ibid.

[41] A point that cannot be grasped if alienated labour is seen as an unmediated expression of the direct domination of the labourer by the capitalist in the process of production, as happens with the orthodox approach. On this issue, see Clarke 1991a, p. 75.

[42] Marx 1992b, p. 319.

So far, then, I have followed Marx's discovery of alienated labour as the concealed foundation of political economy with emphasis on the relation of the worker to the product of her/his labour as an autonomous power. However, this initial expression of alienated labour constitutes only the first of its four determinations. From this initial relation, Marx goes on to describe further developments of this alienation in the relation of the human being to her/his own productive activity (since the alien character of the product of labour cannot but be the outcome of the alien – and hence, forced – character of the productive activity itself); to her/his very species-being (since conscious productive activity is what distinguishes human life from animal life); and to other human beings (since the relation of the human individual to her/his own activity also reveals her/his relation to the activity of other human beings). In all these other forms, the content of the first determination is maintained: these relations take the form of hostile potencies which dominate the human individual. Marx's analysis of the third determination of alienated labour is particularly remarkable since, through its exposition, he presents for the first time the general determinations of human life from his materialist perspective; a conception which would remain basically unaltered throughout the rest of his works, namely, the specific determination of the human being as a *productive* subject or of human individuality as an expression and mode of development of her/his *productive subjectivity*.[43]

The Historicity of the Social Relations of Production and the Determination of Communism as the Supersession of Alienated Labour

The importance and centrality of Marx's discovery of the specific determination of the human being in its productive subjectivity cannot be overestimated. For what is at stake in this insight *is precisely the uncovering of the material foundation from which the revolutionary powers of the proletariat must spring*. Hence, although through this discussion Marx seems to move far away from the concrete question he was trying to answer – i.e. the necessary form of the revolutionary political action of the working class – he actually never lost contact with that immediate problematic. From the methodological perspective of his mature works, one can easily make sense of the role of these reflections. In a nutshell, it seems plausible to read Marx as engaged in the 'analytical moment' of the research process (the movement from the 'concrete' to the 'abstract', in his later terminology). In other words, he was attempting to grasp the more abstract forms that were behind that immediate concrete form that triggered his whole intellectual endeavour, i.e. the will to social transformation of the proletariat.

---

[43] The exposition of the generic determinations of the labour process in Chapter 7 of *Capital*, Volume I (Marx 1976g, pp. 283–90) does not involve any substantive change in comparison with the discussion of the human species-being in the *Manuscripts*. In both cases, the main point is the same: it is the mediation of individual consumption by labour or conscious life activity that distinguishes the human form of the appropriation of nature from its animal form.

Now, this general material content cannot by itself account for the social necessity of the proletariat's revolutionary subjectivity. The relation between the latter and the former is not immediate. To put it simply, the mere fact of being the direct producers whose productive activity – the key mediator in the production of human life – is alienated does not constitute the foundation of the capacity of the workers to abolish alienated labour, that is, of their determination as a revolutionary class.[44] Or, better stated, I shall argue that this fact constitutes the basis for the revolutionary subjectivity of the working class *only with the mediation of the material mutations in their subjectivity* as such direct producers that the historical movement of alienated labour brings about.[45] In fact, the crux of the matter resides precisely in the mediations that make the radical transformation of the mode of development of human productive activity take the form of the revolutionary action of the working class. Evidently, Marx would not solve this question thoroughly in the *Paris Manuscripts*. However, this text is full of interesting insights that, retrospectively, show how Marx was moving in that direction.

The reconstruction of the exposition in the *Manuscripts* reveals that what Marx offers in this text up to this stage is a description of what he discovered as the hidden foundation of the independent movement of private property, i.e. alienated labour. However, it is clear that it is not sufficient for an investigation of the real nature of capitalist society to claim that human subjectivity is realised in this alienated form and to describe the characteristics of this mode of existence of humanity. A real explanation must include an account of *how* and *why* labour becomes alienated. Aware of this situation, Marx poses the question in the following way towards the end of the first manuscript:

---

[44] In this respect, see my discussion of Arthur 1986 below.

[45] To put it in the 'mature' terminology of *Capital*, I shall show that the determination of the working class as a revolutionary subject is not an expression of the *formal* subsumption of labour to capital, but of the *real* subsumption; more concretely, of the productive subjectivity of the latter's most developed form as large-scale industry.

> We have taken the *estrangement of labour*, its *alienation*, as a fact and we have analyzed that fact. How, we now ask, does *man* come to *alienate* his labour, to estrange it? How is this estrangement founded in the nature of human development?[46]

It is my view that the first question leads Marx to the investigation of the specific capitalist form in which social labour is organised, i.e. the social relations of production of capitalist society. The other side of this is the discovery of the general content of the form of social relations that can overcome alienated labour. In turn, the second question leads Marx to try to find the historical reason for the existence of capitalist society (its historical mission in the genesis of communism). Obviously, the answer to these two questions must lie at the very basis of the social determinations of revolutionary subjectivity. I shall argue that in trying to answer these two questions (especially in the case of the second one), Marx's investigation starts to become blurred. The limits of an exposition, which started with the categories and laws of political economy as a given presupposition, become increasingly manifest.

Regarding the first question, it is clear that it is a necessary corollary of Marx's discussion of the determinations of the human species-being. For, although human productive powers are borne by each particular individual, the actualisation of these potentialities characterising the species – i.e. the realisation of the transformative powers of the human being – can only affirm itself through the organic unity of individual lives, through social life. Marx's discussion of scientific activity in the third manuscript amounts to nothing more than this.[47] It is a clear comment on the necessary social character of individual life activity or, seen the other way round, the necessity for the process of social metabolism to be realised through individual life processes.

> It is above all necessary to avoid once more establishing 'society' as an abstraction over against the individual. The individual *is* the *social being*. His vital expression – even when it does not appear in the direct form of a communal expression, conceived in association with other men – is therefore an expression and confirmation of *social life*. Man's individual and species-life are not two *distinct things* …[48]

---

[46] Marx 1992b, p. 281.

[47] See Marx 1992b, p. 350.

[48] Ibid.

In other words, the realisation of the human species-being (and so the development of human productive subjectivity) necessarily takes concrete form in the *social relations of production*, i.e. in the concrete historical form through which society organises the reproduction of its life. Hence, an alienated mode of existence of the human species-being can only have its foundation in the specific historical form of the social relations of production. Consequently, one would expect Marx to proceed to the exposition of the specificity of the capitalist mode of production in order to clarify the source of alienated labour. Unfortunately, this is not the path he follows. Instead, he starts to consider communism as the historical negation of capitalist society and as the supersession of alienated labour. Yet implicit in his discussion of communism lies hidden the specific nature of capitalist relations of production as its opposite. For if Marx considers communism as the becoming fully social of the human individual, it is clear that he is contrasting this unity between the individual and the social character of human activity with their separation in bourgeois society – that is, with the private character taken by social labour. Moreover, as Clarke notes,[49] even if this appears ambiguously in the *Paris Manuscripts*, it is discussed explicitly in the *Comments on James Mill*. In this text, Marx focused on the development of the connection between alienated labour and money. In a nutshell, he dealt with money as the concrete material incarnation of the social powers of alienated labour. And although this idea appears in the *Paris Manuscripts* as well, the importance of the *Comments* is that they present in a clearer form the connection between alienated labour and the most abstract economic forms of capital: the value form and the money form.

> Why must private property finish up in money? Because as a social animal man must finish up in *exchange* and exchange – given the premise of private property being presupposed – must finish up in *value*. For the mediating movement of man engaged in exchange is not a social, human movement, it is not a *human relationship*: it is the *abstract relationship* of private property to private property, and this *abstract* relation is the *value* which acquires a real existence as value only in the form of *money*.[50]

In turn, this investigation leads Marx to posit in a more explicit form the question of the specificity of capitalist social relations of production. Thus, he shows very clearly that the ground of alienated labour lies in the fact that the reproduction of human life is organised through the production and exchange of commodities. In other words, he shows that labour becomes alienated because social labour takes the form of its opposite: private and independent labour. Obviously, this is the terminology of *Capital*. In this earlier text, he still uses a somewhat philosophical language and speaks of the contradictory existence of universal – 'the community' – and particular – 'the human individual'. Thus Marx states:

---

[49] Clarke 1991a, p. 75.

[50] Marx 1992c, p. 261.

> The process of *exchange* both of human activities in the course of production and of *human products* is equal to the species-activity and the species-spirit, whose real, conscious and authentic existence consists in *social* activity and *social* enjoyment. Since the essence of man is the *true community* of man, men, by activating their own essence, produce, create this *human community*, the social being which is no abstract, universal power standing over against the solitary individual, but is the essence of every individual, his own activity, his own life, his own spirit, his own wealth. Therefore, this *true community* does not come into being as the product of reflection but it arises out of the *need* and *egoism* of individuals, i.e. it arises directly from their own activity.[51]

In brief, already at that time Marx discovered that the alienation of human powers as attributes of capital springs from the private form of social production or, what is the same, from the commodity form of social relations.[52] However, neither in the *Manuscripts* nor in the *Comments* does Marx develop this profound insight into the direction which, on its own terms, it demanded, namely, the establishing of the connection between the private character of labour and all the different alienated economic forms which political economy represented with its categories and, more importantly, their historical movement towards their own dissolution through the revolutionary action of the proletariat. Without this link, the critique was condemned to remain too abstract and external. Nevertheless, I think that Marx himself was aware of this necessity and, one may say, took it as a sort of work plan.[53]

---

[51] Marx 1992c, p. 265.

[52] Private property, the general juridical form of this alienation, is always conceived of by Marx as the consequence of private (hence, alienated) labour.

[53] Towards the end of the first manuscript, he states: 'Just as we have arrived at the concept of *private property* through an *analysis* of the concept of *estranged, alienated labour*, so with the help of these two factors it is possible to evolve all economic *categories*, and in

On the other hand, this discovery of the specificity of capitalist social relations made Marx turn his attention to the form of the social life process that negates the alienation immanent in capitalist social forms, i.e. communism. With his discussion of communism as the 'positive supersession of private property', Marx was making an important step forward in the concretisation of the nature of the determinations of the complete human emancipation that he had previously counterposed to the merely political emancipation demanded by the Young Hegelians. In particular, in the *Manuscripts* the content of the supersession of modern society is no longer posited simply in terms of its political forms (true democracy as the abolition of the separation between state and civil society, or *citoyen* and bourgeois), but becomes, in its simplest determination, essentially material/productive (communism or the conscious universal co-operation between the associated producers).

What is, then, according to Marx, the material content of the communist transformation of social life? In the *Manuscripts*, Marx presents his views on the specific determinations of communist social forms after the critical account of the content of communism by previous socialist thinkers. His first statement in this regard is the following:

> *Communism* is the *positive* supersession of *private property* as *human self-estrangement*, and hence the true *appropriation* of the *human* essence through and for man; it is the complete restoration of man to himself as a *social*, i.e. human, being, a restoration which has become conscious and which takes place within the entire wealth of previous periods of development … it is the *genuine* resolution of the conflict between man and nature, and between man and man, the true resolution of the conflict between existence and being, between objectification and self-affirmation, between freedom and necessity, between the individual and the species. It is the solution to the riddle of history and it knows itself to be the solution.[54]

Briefly put, Marx is implying that the production of communism involves the supersession of alienated labour and the full realisation of the human species-being.[55] This is quite a strong statement, so it deserves close scrutiny. Let us

---

each of these categories, e.g., trade, competition, capital, money, we shall identify only a *particular* and *developed* expression of these basic constituents' (Marx 1992b, p. 333).

[54] Marx 1992b, p. 348.

[55] Passages like the one just quoted, when read outside the context of Marx's overall work,

then try to disentangle the meaning of Marx's dense quotation. I have already mentioned that Marx saw the specifically human form of the natural life process in the fact that human beings regulate their process of metabolism through consciousness. That is, they appropriate the objective powers of the environment through the organisation of the externalisation of their own objective, socially developed forces by means of thought, thus giving their life process the form of productive activity, of a labour process. Through this process of appropriation of the objective world, human beings expand their own product-

---

could give the impression that he sees the human essence as a generic content (an abstractly free and creative human subjectivity) that is realised in defective appearances until showing itself immediately as such under communism. The use of phrases like 'restoration of man' can certainly lead to such a reading. Marx's immediate identification of the human individual as a free being (see Marx 1992b, p. 328) – simply by virtue of having conscious life activity – could also be misleading (as accurately noted by Ollman 1971, p. 112). But it is clear from Marx's overall argument that human productive subjectivity (i.e. the human species-being) only exists and develops (and, therefore, is produced and reproduced) *in and through* its historically determined social forms, there being absolutely no exteriority between them. 'Really' free subjectivity is not an abstract human essence that 'returns to itself' after ridding itself of the limitations imposed by 'inhuman' social forms, but a concrete form that the *materiality* of human individuality acquires in the course of its historical process of development when becoming *fully* conscious. Indeed, under those circumstances the human individual embodies the potentiality consciously to affirm her/his *historically achieved* material powers of the species in their plenitude, i.e. universally. On the other hand, it is self-evident (but a triviality) that the concrete form of freedom acquired by human life in history must be a potentiality intrinsic to its species-determination, in the same way that it is a real material potentiality of the caterpillar to become a butterfly. The recognition of this does not amount to any sort of abstract, ahistorical 'essentialism'. On the other hand, however, this does not make human freedom the content or substance striving for realisation in the course of history. The latter, essentially Hegelian, view is precisely the approach ridiculed by Marx and Engels in their critique of the Young Hegelians in *The German Ideology* (see especially their critique of Stirner in Marx and Engels 1976a, p. 254). And yet, as we shall see in the second part of the book, one could argue that it is precisely that view that, implicitly or explicitly, underlies most contemporary Marxist approaches to the determinations of revolutionary subjectivity, seen as the expression of the affirmation of an abstractly free humanity ridding itself of capitalist forms of social mediation, the opposite of its capital-determined, alienated form of existence. See Clarke for a critique of those approaches in relation to the *Paris Manuscripts* (1991a, pp. 64–6). In terms of readings of *Capital*, the Marxist-Humanist current associated with Dunayevskaya is particularly expressive of this 'materialist' appropriation of the Hegelian dialectic of freedom as the substance of human history and, hence, of revolutionary subjectivity (see Dunayevskaya 1988 and 1989, Chapters 1 and 2; see also the excellent critique of this aspect of Dunayevskaya's thought by Paul Mattick 1958).

ive powers and, therefore, their capacity to regulate the metabolic 'dialogue with nature' by means of conscious activity. Hence, Marx's reference to the 'strife between existence and essence' can only mean that, before the advent of communism, the development of that human potentiality to act consciously and universally upon nature takes the concrete form of its own negation. In pre-capitalist social forms, this negation is the result of the restriction of the manifestation of human life within particularistic boundaries. Modern capitalist society develops and mobilises the universality of human powers, but only to negate their immediate manifestation as such, through their inversion as powers borne by the product of labour. As the negation of this negation, communism involves giving both 'subjective and objective nature' a 'form adequate to the *human* being'.[56] Hence a first determination of communism must be the development of productive subjectivity in a form adequate to the display of the universality of its 'mastery over natural forces, of his own nature as well of those of so-called "Nature" ',[57] i.e. as directly taking the form of the universal 'self-confirmation' of human productive powers in and through the subjectivity of each human individual.

On the other hand, we have seen that, according to Marx, the affirmation of human productive powers and, therefore, the development of productive consciousness, can only assert itself through the integration of the individual processes of metabolism into a process of social metabolism, that is, through social productive co-operation. In other words, the human being is, by its very nature, a *social* being. This means that the development of that potential universality of productive subjectivity can only take concrete form through the universality of social relations. Again, 'private property' develops this universal sociability but only in the form of estrangement, that is, as universal relations of atomisation and separation between human beings. Communism, as the determinate negation of the rule of private property, can only mean the positing of this universal sociability as a direct, conscious determination of social existence.

The fact that in the third manuscript Marx takes stock with Hegel's reduction of human (productive) subjectivity to knowing self-consciousness and, in particular, with the abstraction 'absolute knowing' as the *speculative* identity of thought and being, should not blind us to the centrality of consciousness to the social transformation which brings about the communist constitution of social life. If 'it is true that thought and being are *distinct*, but at the same time they are in unity with one other',[58] this can only imply that the form of human subjectivity that results from the immediate positing of the human individual as a social being must involve the complete awareness of this necessarily social character of individual life. In a passage where Marx anticipates his well-known dictum that social existence determines social consciousness, he states:

---

[56] Marx 1992b, p. 391.

[57] Marx 1993, p. 488.

> As *species-consciousness* man confirms his real *social life* and merely repeats in thought his actual existence; conversely, species-being confirms itself in species-consciousness and exists for itself in its universality, as a thinking being.[59]

It is crucial to bear in mind Marx's emphasis on the human individual's consciousness of its own social determinations as a fundamental condition for the communist form of productive association. This is the reason why Marx states that not only is communism the solution to the riddle of history, but it also '*knows* itself to be this solution'. As a consequence of this, it is clear that the revolutionary subjectivity that produces the communist society must be the bearer of a consciousness that is fully aware of the socio-historical necessity of its action. *Revolutionary action is such for being a fully conscious action.* For the communist 'thinking consciousness',

> The entire movement of history is therefore both the *actual* act of creation of communism – the birth of its empirical existence – and … the *comprehended* and *known* movement of its *becoming*.[60]

In brief, Marx now clearly sees that the transcendence of this inverted social existence has its content in the transformation of the economic forms of society (although this obviously involves the transformation of the whole of social life). Thus he discovers the material content of the proletarian revolution and, therefore, of the form of social life that supersedes capital, i.e. communism, as the conscious, directly social productive association of individuals.

This leads us to the second question that follows from the determination of communism as the conscious realisation of the social being of the human individual. For it should be clear by now that the communist constitution of social life involves a transformation of the forms of human subjectivity and, therefore, of the forms of human consciousness. Now the question arises as to the specific character of this revolutionary consciousness that becomes aware of the social necessity of its action. Is it just an immediate consciousness, which can discover the determinations of its social being through *mere* intuition or feeling? Or is it a mediated form of consciousness? And in this latter case, is it a scientific consciousness or a philosophical one? I shall give a more complete answer to this question during the course of this book. But from what has already been anticipated above regarding Marx's critique of philosophy as a developed expression of the alienated consciousness, it seems fair to narrow the question down to the dichotomy between seeing revolutionary consciousness as an expression of immediate intuition or as a scientifically mediated form of subjectivity. The following passage, I think, speaks quite eloquently in favour of the latter:

---

[58] Marx 1992b, p. 351.

[59] Marx 1992b, pp. 350–1.

[60] Marx 1992b, p. 348.

> But natural science has intervened in and transformed human life all the more *practically* through the industry and has prepared the conditions for human emancipation, however much its immediate effect was to complete the process of dehumanization. Industry is the *real* historical relationship of nature, and hence of natural science, to man … Natural science … has already become – though in an estranged form – the basis of actual human life. The idea of *one* basis for life and another for *science* is from the very outset a lie.[61]

As Marx states very clearly, the scientific transformation of human life already happening under the rule of 'private property' constitutes the necessary preparation of the material basis for human emancipation. It is clear then that the consciousness that arises out of this new form of 'industry' in order to emancipate it from its alienated mode of existence must be a scientific one, since there 'cannot be a different basis for life and science'. This is why Marx is very explicit in recognising the progressive role of private property in the historical development of human productive subjectivity. Moreover, it is on these grounds that he criticises those crude, romantic versions of communism that, in light of the inhuman consequences of the alienated form of existence of the scientific appropriation of the powers of nature, want to negate 'the entire world of culture and civilisation', and to return to 'the *unnatural* simplicity of the *poor*, unrefined man who has no needs and who has not even reached the stage of private property, let alone gone beyond it'.[62] Needless to say, this has nothing to do with a positivistic technocratic utopia, built on the basis of the existing forms of natural-scientific consciousness. Quite to the contrary, Marx is very emphatic that the emancipation of humanity does not simply involve the de-subordination of natural science to the requirements of the alienated movement of private property, but also *the transformation of the very nature of scientific consciousness itself*. This new form of science, on the basis of which the revolutionary subjectivity will be able to achieve the communist transformation of society, Marx refers to as the 'human natural science, or the natural science of man,' or, simply, 'true human science'. In Marx's view, it will comprise the totality of what in its alienated form of existence appears as the different objects of distinct forms of science (the natural and the social), on the one hand; and as a purely theoretical activity, on the other, 'since true practice is the condition of a real and positive theory'.[63] Its basic principle, discovered in its general form by Feuerbach, consists in putting at the centre of the inquiry 'the social relation of "man to man"'.[64] Yet, as I shall argue, this basic principle as such would prove insufficient to give the revolutionary science its adequate form.[65]

---

[61] Marx 1992b, p. 355.

The Determinations of the Revolutionary Subjectivity of the Proletariat and the Limits of the *Paris Manuscripts*

In the previous section, I left a question unanswered, namely, Marx's explanation of the necessity of alienation in human historical development. In other words, the issue at stake is the grounding of capital's historical *raison d'être* and, therefore, of its overcoming. Having shown how, for Marx, the realisation of the human species-being can only be the product of historical development, it is clear that he is not suggesting that it is a contingent and extrinsic tragedy imposed onto an otherwise eternally free human essence and that it is a matter of recovering a pure subjectivity oppressed by private property. The alienated existence of human subjectivity must play a determinate role in its development. Moreover, it is precisely the fulfilment of this role that has to constitute the necessary condition for its historical supersession. This is what links the future and the present so that the former is not just a utopian project but finds the conditions for its emergence immanent in the historical movement of bourgeois society. In this sense, for Marx freedom can only be the result of a 'self-superseding movement', which 'will in reality undergo a very difficult and protracted process' of social transformation.[66] In turn, this theme is immediately linked with the question of the determinations of the revolutionary subjectivity of the proletariat. For if the working class is the historical subject whose revolutionary action is to achieve the abolition of alienated labour, this can only mean that those conditions which private property engenders in the course of its development, and which generate the necessity of its own dissolution as a form of existence of human subjectivity, are necessarily activated through the political action of the former.

---

[62] Marx 1992b, p. 346.

[63] Marx 1992b, p. 364.

[64] Marx 1992b, p. 381.

[65] More concretely, following one of the key contributions of Iñigo Carrera (2014), I shall argue that the transformation at stake of the nature of science concerns its very form, i.e. its method. A 'true human science' can develop such a revolutionary content only by virtue of its *dialectical* form.

I would like to argue that it is especially in this aspect of Marx's early critique that its abstract character is most strongly felt and the course of his exposition becomes increasingly blurred. As we shall see, in the *Manuscripts* Marx was unable to develop the mediations that connect the revolutionary transformation of the forms of social life required by the further development of the materiality of the human species-being with the political action of the workers.

Yet this does not mean that no evolution obtains with respect to Marx's previous formulation, which posed the question in terms of the realisation of philosophy. An expression of the novel insights developed can be read in Marx's critique of other socialist thinkers:

> But the antithesis between *propertylessness* and *property* is still an indifferent antithesis, not grasped in its *active connection*, its *inner* relation, not yet grasped as a *contradiction*, as long as it is not understood as the antithesis between *labour* and *capital*.[67]

This passage can be taken as a kind of self-criticism of his previous views on social transformation. For the antithesis between lack of property and property is what he posited in the *Introduction to the Contribution to the Critique of Hegel's Philosophy of Right* as the ground for the revolutionary subjectivity of the proletariat. Since he showed that private property is only the juridical expression of alienated labour, it is clear that the overcoming of alienation can only spring from the abolition of the latter. Without the annihilation of the alienated character of productive activity, the juridical elimination of private property can only lead to another form of the reproduction of alienated labour, one in which

---

[66] Marx 1992b, p. 365.

[67] Marx 1992b, p. 345.

> [t]he community is simply a community of *labour* and equality of *wages*, which are paid out by the communal capital, the *community* as the universal capitalist. Both sides of the relation are raised to an *imaginary* universality – *labour* as the category in which everyone is placed, and *capital* as the acknowledged universality and power of the community.[68]

On the other hand, by posing the question in terms of alienated labour, he eliminates the externality between the revolutionary subjectivity of the proletariat and capitalist social forms that characterised his previous formulation. That is, from an abstract negation of capital, revolution becomes its determinate negation. Whereas before he conceived of the proletariat as being excluded from the general social relation of modern society (private property) and founded his revolutionary role precisely in this social existence alienated from society (propertylessness), he now sees the worker as *within* the general social relation of bourgeois society (alienated labour or capital). So much so that in the second manuscript Marx shows that the inversion between subject and object is so real to the point of directly turning the conscious existence of the worker into a mode of existence of capital.

> The worker is the subjective manifestation of the fact that capital is man completely lost to himself, just as capital is the objective manifestation of the fact that labour is man lost to himself. But the *worker* has the misfortune to be a *living* capital …[69]

Instead of deriving the proletariat's revolutionary being from the universal exclusion from the specific, alienated social relations governing modern society (and therefore from some sort of pure subjectivity uninfected by private property), he came to derive it from the proletariat being the concentrated, active incarnation of the former. Hence, the externality between labour and capital is eliminated and they are now seen in their necessary, albeit contradictory, unity. It is this contradictory character, deriving from the fact that human productive subjectivity develops its powers as an attribute of its product that gives alienated labour its dynamic, self-moving character that drives it into its own dissolution. And Marx makes explicitly clear that the revolutionary movement can only derive its transformative powers from the historical movement of this alienated social existence.

---

[68] Marx 1992b, pp. 346–7.

[69] Marx 1992b, p. 335.

> It is easy to see how necessary it is for the whole revolutionary movement to find both its empirical and its theoretical basis in the movement of *private property* or, to be more exact, of the economy.[70]

Simply put, what this means is that the consciousness of the workers is a concrete form of the alienated consciousness. And this holds for both the forms of working class subjectivity that reproduce the movement of alienation and that which develops the historical powers necessary to abolish it, that is, *revolutionary consciousness*.

This crucial point is correctly highlighted by Mészáros's detailed study on the *Paris Manuscripts* when he states that the revolutionary consciousness is not a free, non-alienated consciousness, but a 'consciousness of being alienated'.[71] However, this insight is not argued on the grounds of the development of the concrete determinations of the alienated consciousness that make it become conscious of its own alienation. The reason he gives is purely formal and comes down to the fact that if the movement of the alienated consciousness did not produce the awareness of its own social existence, the conscious transformative action aiming at its transcendence would be impossible. Thus he states:

> Were society an 'inert totality of alienation', nothing could possibly be done about it. Nor could there be any problem of alienation, or awareness of it, for if consciousness were the consciousness of this 'inert totality' it would be one with alienation … not a consciousness that reveals and opposes – in however abstract a form – the alienated nature of this inert totality. Alienation is an inherently dynamic concept: a concept that necessarily implies change. Alienated activity not only produces 'alienated consciousness', but also the 'consciousness of being alienated'. This consciousness of alienation, in however form it might appear … not

---

[70] Marx 1992b, p. 348.

[71] Mészáros 1970, p. 181.

> only contradicts the idea of an alienated inert totality, but also indicates the appearance of a *need* for the supersession of alienation.[72]

This is certainly true, but it is close to a truism. That is, once we correctly highlight that there is no 'outside' from which to dissolve this alienated social existence, and that this is a transitory, historical phenomenon that is bound to disappear, it is evident that it must be the movement of alienated activity itself that produces the antagonistic form of alienated consciousness capable of putting an end to alienation. The question is about the concrete forms in which this negation of the negation asserts itself. Thus stated, Mészáros's argument simply involves a purely logical necessity. Moreover, what is of interest here is the *concrete*, fully developed revolutionary consciousness of this alienated social existence and not one that opposes it in 'however abstract a form'.[73] This is not for any scholastic reasons but because this study searches for the determinations of the transformative action of the proletariat embodying the social powers that enable it to abolish alienated labour. Hence, I do not find satisfactory the only reference to the materiality of social life that this author puts forward in simply arguing that 'needs produce powers just as much as powers produce needs'.[74] For the central question remains unanswered: what are the concrete social determinations of the *materiality of the productive subjectivity of the labourers* that give those very same 'powers and needs' a conscious revolutionary form? No response to this crucial question can be found in Mészáros's reading of this early text. As a matter of fact, he ends up offering a *moral* basis for the necessity of transcending the alienated forms of bourgeois society. More problematically, he even states that after the abolition of alienation, not only does morality persist but so too does the legal form.[75]

Without entering into a detailed assessment of the merits and limitations of Mészáros's own account, let me just point out that, at least from the exegetic point of view, this grounding of the revolutionary subjectivity of the proletariat on a moral necessity is completely misguided. As matter of fact, Marx makes the explicit critique of moral consciousness as an uncritical form of the alienated consciousness. Thus he states:

---

[72] Ibid.

[73] Ibid.

[74] Ibid.

[75] Mészáros 1970, pp. 186–9.

> It is inherent in the very nature of estrangement that each sphere imposes on me a different and contrary standard: one standard for morality, one for political economy, and so on. This is because each of them is a particular estrangement of man and each is centred upon one particular area of estranged essential activity; each is related in an estranged way to the other …[76]

Mészáros is aware of this Marxian critique of morality as an uncritical expression of alienation.[77] But he reads Marx as implying that what is wrong is not morality *per se* but the abstract, transcendental form of the moral argument. One, precisely, that abstracts from the material questions that political economy deals with. For him, the unalienated moral consciousness is that which, while still arguing in terms of moral evaluation, critically reflects upon those material questions of the concrete life activity of human beings, e.g. the nature of productive activity. Yet I think that the quotation is quite revealing as a critique of moral standards altogether as the basis for any action aiming to revolutionise the alienated conditions of social life.

Although Mészáros's recourse to a moral necessity as the ground for the revolutionary subjectivity of the proletariat is unacceptable, his inability to find a consistent account of its determinations in the *Manuscripts* is, to some extent, understandable. For one of the problems of this early text is precisely its lack of a rigorous exposition of those social determinations and their historical genesis through the unfolding of the contradictions of alienated social life. This does not imply that no reference to this problematic can be found. Certainly, as commented above, Marx was well aware of the need to address this question. But the problem resides in the unsatisfactory character of his attempt at an explanation, derived, in turn, from the limitations of Marx's own comprehension of the 'laws of motion' of alienated labour at that time.

What, then, is Marx's account of the necessity of alienated labour and its transcendence in the *Paris Manuscripts*? It is difficult to find a straightforward answer to this question, since Marx's own discussion is unclear and hesitant. Thus he seems to oscillate between different grounds for the workers' revolutionary subjectivity. Now, I would like to argue that behind this insufficiency of Marx's exposition we can find the methodological limitations of this early text. For a satisfactory account of this problematic would have required the deployment of the critical power of the dialectical method understood as the 'reproduction of the concrete by means of thought'. This is the method that Hegel deployed, albeit in a mystified form, in his *Science of Logic*. The critical appropriation of Hegel's discovery fully crystallised only some years later in Marx's life through the development of his 'mature' critique of political economy. Regarding the question of the abolition of alienated labour, Marx's appropriation of the insights developed by Hegel related more to the 'materialist inversion' of Hegel's account of the historicity of the forms of human subjectivity and their historical development through the process of self-alienation and its transcendence:[78] hence Marx's account of the reason to be of private property. In a quite Hegelian fashion, he grounds the necessity of alienation in a very abstract and general dialectic, as a kind of movement of engendering a determinate negation through the previous development of its opposite into its plenitude. What Hegel essentially sees in terms of an abstract mental labour, that is, as a movement of consciousness, Marx grasps in its reality as the historical movement of real, sensuous productive activity of human beings.[79] Yet he takes from Hegel's account the validity of the general form of the historical movement in the 'dialectic of negativity as the producing principle'.[80] Although in the *Phenomenology* 'the various forms of estrangement which occur are therefore merely different forms of consciousness and self-consciousness',[81] Hegel has the merit of conceiving

---

[76] Marx 1992b, p. 362.

[77] Mészáros 1970, p. 187. To be more exact, moral consciousness is the alienated consciousness of the commodity producer who, unaware of the social determinations of her/his life activity, sees her/his social being as an external force standing over and against her/his apparently independent individuality in the form of an 'ought to be'. See Iñigo Carrera 2007, pp. 64–5.

> the self-creation of man as a process, objectification as loss of object [*Entgegenständlichung*], as alienation and as supersession of this alienation; that he therefore grasps the nature of *labour* and conceives objective man – true, because real man – as the result of his own labour.[82]

---

[78] And yet, I shall argue in the next chapter that, already in the *Paris Manuscripts* – more precisely, in the section discussing Hegel's *Logic* – Marx initiated the critical appropriation of the rational kernel of the dialectical method as developed by Hegel.

[79] For a good discussion of this aspect of the young Marx's critique of Hegel, which avoids the misreading of existential and phenomenological Marxism, see the already cited work by Arthur (1986).

[80] Marx 1992b, pp. 385–6.

[81] Marx 1992b, p. 385.

[82] Marx 1992b, p. 386.

It is this form of the Hegelian 'dialectic of negativity' that Marx uses to account for the necessity of the historical dynamic of alienation and its supersession. For he seems to suggest that private property is necessary insofar as the human species-being, in order to develop the plenitude of its powers to objectify itself, must first negate itself as a fully conscious social productive activity, thus affirming itself as alienated, unconsciously social activity. In turn, only after the expansion and generalisation of private labour – hence, of private property – and the consequent plenitude of alienation, can the moment of negation of the negation emerge.

> The *real, active* relation of man to himself as a species-being, or the realization of himself as a real species-being, i.e. as a human being, is only possible if he really employs all his *species-powers* – which again is only possible through the cooperation of mankind and as a result of history – and treats them as objects, which is at first only possible in the form of estrangement.[83]

We can see that the movement is presented as following an abstract and generic 'dialectical' necessity. This is not necessarily wrong as a formal description of the movement of the self-production of humanity, but it is precisely its generality that makes it insufficient to account for the concrete determinations that we are searching for. In other words, this general dialectic lacks any concrete specificity regarding the form of motion of the annihilation of capital through the revolutionary action of the working class.[84] This led Marx to offer several grounds for the proletariat's revolutionary subjectivity. The reason for this is that every extreme manifestation of the alienated social existence (whether progressive or not) can be seen as a symptom of that state of plenitude and could therefore fit into that general scheme as the condition for the emergence of the revolutionary powers of the workers. One instance of this can be found in the passages I have already referred to regarding Marx's views on a 'truly human science'. There he argues that since the universal alienation in the object leads to the development of 'industry' and the consequent coming into being of the complete humanisation of nature, it must engender the scientific consciousness which eventually frees itself from all traces of its alienated existence through the practical abolition of private property.[85] That is, it is the generalisation and complete intensification of inhumanity that produces the constitution of real humanity. As he states some pages later in the section called *Money*:

---

[83] Ibid.

[84] One can say that in the *Manuscripts* Marx is guilty of the charges made by Dühring of externally imposing the negation of the negation on history. Engels correctly points out why this is not the case of *Capital*. See Engels 1975, pp. 107–12.

> Only through developed industry, i.e. through the mediation of private property, does the ontological essence of human passion come into being, both in its totality and in its humanity; the science of man is therefore itself a product of the self-formation of man through practical activity.[86]

In another instance, he poses this movement as pertaining to the development of the totality of the physical and intellectual senses of the human being.[87] These can develop in a truly human form only after acquiring an alienated mode of existence whose synthetic expression is their one-sided subordination to the sense of having. Again we see the general dialectic at work:

> Therefore *all* the physical and intellectual senses have been replaced by the simple estrangement of *all* the senses – the sense of *having*. So that it might give birth to its inner wealth, human nature had to be reduced to this absolute poverty.[88]

Marx, somehow idealistically, also fits the 'self-development of communist consciousness' into this general scheme. In his critical account of the different forms of communist consciousness, he states that 'the supersession [*Aufhebung*] of self-estrangement follows the same course as self-estrangement'.[89] He seems to be arguing that, in order to develop itself, truly communist consciousness must first negate itself as the real determinate negation of private property by taking some undeveloped form. In the form of 'crude communism', the political programme put forward would not lead to the abolition of private property, but to its generalisation.[90] This 'first positive abolition of private property' is partially negated by those forms of communistic consciousness that, although clear about the necessity to abolish private property (instead of equalising its distribution) as the form of superseding human self-estrangement, are 'still held captive and contaminated by private property'.[91] Finally, communist 'thinking consciousness' develops the plenitude of its critical powers completely to abolish alienated labour. In this form, it no longer represents the abstract negation of private property, but its determinate negation and therefore its truly positive supersession.[92]

---

[85] Marx 1992b, p. 355.

[86] Marx 1992b, p. 375.

[87] Marx 1992b, pp. 351–4.

[88] Marx 1992b, p. 352.

[89] Marx 1992b, p. 345.

[90] Marx 1992b, p. 346.

Marx thus alternates between different foundations for the social necessity of abolishing alienated labour without offering a solid ground for this process of social transformation. Moreover, there is no account of the different stages through which alienated social development must pass before attaining its communistic form, or of the role of the political action of the workers – the class struggle – in that contradictory process. Marx just states the necessity of the starting point and the finishing line. But he does not demonstrate the genesis of either of them. What is worse, there is no real mediation between that material ground for the abolition of private property and the subjectivity of the labourers. The need for such mediation is correctly identified by Arthur:

> [T]here are two levels of necessity for the overthrow of private property: (a) abstractly, there is the need to restore man to himself subsequent to the supersession of the system of estrangement; (b) concretely, there is the process whereby capital in its own development leaves the proletariat with no other option than to take the struggle against alienation to its conclusion through identifying the problem as capital, itself the product, expression and mediation of alienated labour.[93]

The key, as far as revolutionary subjectivity is concerned, is, precisely, the mediation between these two points. In the *Manuscripts*, the only connection in this regard is that condition (a) refers to the development of productive subjectivity and, regarding point (b), that the proletarians are the class of direct producers. Thus the emancipatory mission of the proletariat is derived from their being the active incarnation of the estranged relation to productive activity which lies at the basis of all forms of alienated social existence due to the 'ontological centrality' of labour in the constitution of social being.

---

[91] Marx 1992b, pp. 347–8.

[92] Marx 1992b, p. 348.

[93] Arthur 1986, p. 40.

> It further follows from the relation of estranged labour to private property that the emancipation of society from private property, etc., from servitude, is expressed in the *political* form of the *emancipation of the workers*. This is not because it is only a question of their emancipation, but because in their emancipation is contained universal human emancipation. The reason for this universality is that the whole of human servitude is involved in the relation of the worker to production, and all relations of servitude are nothing but modifications and consequences of this relation.[94]

Arthur is right in pointing out that we should not read Marx as implying that the identification of the proletariat as the 'class of the future' is based on its universal suffering, as a 'matter of a sympathetic identification with their problems'.[95] However, I disagree with this commentator's view that Marx's grounding of the revolutionary nature of the proletariat in its 'strategic position in the economic order' where productive activity is the 'key social mediator', suffices as an explanation of the social determinations of the revolutionary subjectivity. This explanation must include the positive exposition about the forms of capital's development that produce in the workers not only the will to social transformation but also the material powers to achieve it. And it is this latter investigation that is missing in the *Manuscripts*. What is more, the materiality of the conditions generating Arthur's 'abstract necessity (a)' seems to stand in blatant contradiction to the barbaric materiality of the life conditions of the workers that Marx described to be the result of the movement of private property. Hence, it is not clear how that 'abstract level of necessity for the overthrow of private property' can be activated concretely in the subjectivity of the workers. In other words, how to reconcile that revolutionary scientific consciousness that discovers the necessity to abolish capital with the brutalised state to which the workers are condemned by the division of labour of manufacture? How to turn the degradation of the physical and intellectual senses of the workers into that fully developed human sensuousness that Marx claimed to be a necessary prerequisite for the emergence of communism? As Markus points out,

> [T]here seems to be no imaginable practico-political strategy, able to bridge this gap and to render the initial contact between theory and

---

[94] Marx 1992b, p. 333.

[95] Arthur 1986, p. 145.

> practice, between the actual situation of the revolutionary subjects and the radical content of the theory possible.[96]

No wonder, then, that in attempting to offer this mediation, Marx only deploys again that generic dialectic of generation through extreme negation of the previous stage. Without a detailed positive account of the laws of motion of alienated labour and the determinations of the political action of the workers as personifications of the former, no significant guide to action can be drawn from revolutionary theory. Or, better stated, from a too general and undifferentiated account of the nature and movement of capitalist society, only an overly general and abstract political programme can be advanced: abolish alienated labour! The scientific critique of capital was bound to remain external and thus impotent to fully unite with practice.

---

CHAPTER 2

The Overcoming of Philosophy and the Development of a Materialist Science

Introduction

In the first chapter I have traced Marx's initial discovery of the proletariat as the revolutionary subject. My partial conclusion was that the *Paris Manuscripts* represented an enormous breakthrough in Marx's intellectual development. More concretely, I attempted to show that in that text one can find Marx's first attempt at a materialistic perspective on the determinations of the revolutionary subjectivity of the working class. However, I also argued that this first step did not solve all the questions that it had set out to answer. Rather, this early text can be seen as laying the foundations for the future research that he would undertake throughout the rest of his life. The *Paris Manuscripts* may be thus seen as both asking the correct questions and giving the *general* direction to be followed in order to find the social determinations of the revolutionary political action of the proletariat. That approach, I argued, consisted in focusing on the development of the materiality of human productive subjectivity in its historically specific forms as the basis for any investigation about the transformative powers of human action. However, I also showed that beyond a certain point Marx's exposition became incapable of further advancing his discoveries. In brief, I tried critically to engage with this 'early Marx' in order to highlight both the insights and limitations to be found at that stage of his development of the critique of political economy in the light of its developed form in *Capital.*

Regarding the merits of the *Paris Manuscripts*, I pointed out that one of the crucial steps forward made, which marked a difference in relation to his previous writings, was the definitive abandonment of the standpoint of philosophy. In other words, I claimed that Marx's adoption of a materialist perspective was tantamount to the transcendence of philosophy. On the other hand, I argued that most limitations of Marx's early critique could be explained by the inadequacy of the transformative method inherited from Feuerbach as the revolutionary form of the proletarian science.

In the previous chapter, these two rather strong claims were just tangentially touched upon. It is a first aim of this chapter to give those assertions closer scrutiny. I shall show that, in fact, both aspects are interrelated. This

is because, although Marx's positive development throughout the whole of the *Paris Manuscripts* already moves beyond the philosophical discourse, it is not until the third manuscript that he feels the need explicitly to address the question of the status of philosophical thinking. Initially, Marx develops this investigation through the critique of the Hegelian dialectic from a still Feuerbachian methodological perspective. However, in the very course of his discussion, he becomes aware of both the limitations of Feuerbach's materialist 'transformative criticism' and the critical power which, once purged from its idealist inversions, could be found in the dialectic. As we shall see, from this moment onwards, Marx's scientific enterprise consisted in further developing this insight up to the point of giving the critique of political economy a fully developed dialectical form.

The Need to Come to Terms with Hegel's Philosophy

As Arthur suggests, Marx's turn to the critique of the Hegelian dialectic in the *Paris Manuscripts* seems to be quite abrupt. In effect, up to that point Marx had been developing his first critical confrontation with political economy along Feuerbachian methodological lines.[1] More concretely, a look at the original order in which Marx developed his argument (different from the one in which it was published), shows that this sudden turn occurs in the context of the discussion of the historical movement leading to the supersession of alienated labour in communism. It is at that point that he veers radically, momentarily leaving behind the critique of economic categories, in order to develop

> by way of explanation and justification … some considerations in regard to the Hegelian dialectic generally and especially its exposition in the *Phänomenologie* and *Logik* and also, lastly, the relation (to it) of the modern critical movement.[2]

How are we to understand this abrupt change in Marx's object of criticism? In his detailed commentary on the *Paris Manuscripts*, Arthur gives a plausible explanation for this. According to him, in discussing the process of the genesis of man as man (the historical realisation of the human species-being), Marx became aware of the formal similarity between that movement and the one Hegel attributes to the absolute spirit in his *Phenomenology of Spirit*.[3] Both involve a process of immediate unity between subject and object, a stage of opposition or radical difference and a recomposition of that unity but now as a mediated unity, in which both the subject and the object appear as the former's own product. In other words, in both cases we are facing a process of historical self-production. The difference between them lies in their views on which is the subject: absolute spirit for Hegel, and the human being as a natural productive being for Marx.

---

[1] Arthur 1986, p. 45.

[2] Marx 1992b, p. 379.

Whilst I do not want to deny the exegetical accuracy of this line of argument, I think that it is not the most fruitful way of approaching the question. First, this materialist appropriation of Hegel's historical dialectic, although important for Marx's discovery of communism as the immanent result of the historical development of human productive subjectivity in its alienated capitalist form, eventually proved incapable of grounding the revolutionary subjectivity of the working class. As I have already mentioned, that abstract dialectic could only account for the general form of movement of the development of human productive subjectivity up to the negation of its alienated form, but could not explain the concrete forms through which it unfolds in the course of history. In other words, that abstract dialectic did not say anything about the specific 'laws of motion' presiding over the movement of modern society. And neither did it explain the concrete historical genesis of the capitalist mode of production and, therefore, its concrete role in the 'natural history' of human productive subjectivity. In fact, we shall see that as Marx advanced in the scientific cognition of the concrete determinations of the movement of capital (and therefore, of the concrete determinations of the development of the conscious revolutionary action of the proletariat), he progressively dropped the recourse to that general dialectic as the ground for the abolition of capital. Hence, whatever the role it played in 1844, that 'materialist inversion' of the formal movement of Hegel's *Phenomenology of Spirit* played no significant part in Marx's subsequent intellectual development.

In the second place, although in the *Paris Manuscripts* Marx clearly started his critique of Hegel with a critique of the latter's *Phenomenology of Spirit*, he also engaged with Hegel's *Science of Logic*. And it is especially with the latter critique that Marx became aware of the essential character of philosophy as uncritical alienated thought. By converting logic into ontology, Hegel actually took philosophy to its necessary extreme, thereby exposing the idealist inversion inherent in all forms of philosophical thought. While other philosophers dogmatically and extrinsically imposed a general logical necessity upon the movement of real concrete forms, according to Marx, Hegel went further and self-consciously took the movement of pure logical forms as constituting or engendering the more abstract content of the real itself. In an absolutely inverted form, Hegel thus claimed to have eliminated the exteriority between the form and content of scientific knowledge, between method and object of cognition.[4]

---

[3] Arthur 1986, p. 46.

As I shall try to show, this confrontation with Hegel's *Science of Logic* was crucial for Marx's discovery of the revolutionary essence of 'the reproduction of concrete by means of thought' – i.e. dialectical cognition – as the necessary method of science determined as practical criticism. A one-sided emphasis on Marx's materialist inversion of the form of motion of Hegel's *Phenomenology of Spirit* overlooks this crucial step in Marx's advance in the production of the critique of political economy as the scientific revolutionary consciousness of the proletariat.

Hence, to the implicit reason behind Marx's engagement with Hegel's thought mentioned by Arthur, I think it necessary to add the explicit one put forward by Marx himself in the opening passages of that section. There he states:

> Modern German criticism was so pre-occupied with the old world, and so entangled during the course of its development with its subject-matter, that it had a completely uncritical attitude to the method of criticism, and was completely unaware of the seemingly formal but in fact essential question of how we now stand in relation to the Hegelian dialectic. The lack of awareness about the relation of modern criticism to Hegelian philosophy in general and to the dialectic in particular has been so

---

[4] On this particular point, Marx was simply following Feuerbach's groundbreaking path, for whom Hegelian philosophy represented the 'culmination of modern philosophy'. See Feuerbach 1986, p. 31. The difference between them, as I argue below, is that Feuerbach's critical supersession of Hegelian philosophy remained essentially philosophical. His 'new philosophy' entailed 'the *realization of* the Hegelian philosophy or, generally, of the philosophy that prevailed until now', albeit one which 'is at the same time the *negation*, and indeed the negation *without contradiction*, of this philosophy' (Feuerbach 1986, p. 31, original emphasis). In contrast, my claim is that Marx's overcoming of Hegelian's inverted dialectic involved the overcoming of philosophy as such, precisely through a materialist appropriation of the critical power of the dialectical method.

> pronounced that critics like Strauss and Bruno Bauer are still, at least implicitly, imprisoned within Hegelian logic …[5]

According to this passage, what moved Marx to a critical engagement with Hegel's philosophy is the fact that the critical form of consciousness prevailing in Germany at that time, far from going beyond the Hegelian mystification of the dialectic, was actually reproducing it 'word by word'.[6] The motivation, then, was not abstractly theoretical, but political through and through. In this sense, it is important to remember the domination by the Young Hegelians of the radical circles in Germany.[7] In particular, Marx is reproaching 'modern German criticism' for the fact that, by 'becoming imprisoned within Hegelian logic', their critique of modern society remains inevitably *philosophical*, that is, incapable of developing into *practical* criticism involving the radical transformation of the existing state of affairs. Instead of leading to the practical abolition of the contradictions of modern society, 'absolute Criticism' ends up trapped 'into the *single* dogmatic antithesis of its own cleverness and the stupidity of the world', which stubbornly remains indifferent to the 'absolute truths' discovered by the former.[8]

But why is philosophical critique necessarily incapable of achieving a radical transformation of the world? Is that not a specific problem of Hegel's *idealist* philosophy, which can be overcome by replacing it with a *materialist* one? As stated above, Marx's critique of Hegel's philosophy actually involved the critique of philosophy as such: this is because, as we shall see, Hegel is considered by Marx to be the one who pushed philosophy to its limits, unconsciously laying bare its essential nature as

> nothing else but religion brought into thought and developed in thought, and that it is equally to be condemned as another form and mode of existence of the estrangement of man's nature.[9]

Therefore, a truly critical appropriation of Hegel's thought could only mean for Marx the transcendence of the philosophical standpoint *tout court*. For how can a mode of existence of the alienated consciousness, intrinsically bound to uncritically express human alienation, be the basis for its supersession? The

'establishment of *true materialism* and of *real science*'[10] initiated by Feuerbach, and which Marx attempted to bring to completion, was incompatible with the starting point of philosophical reflection. A real science, Marx learnt from Feuerbach, can only have as its point of departure 'the social relationship of "man to man"'.[11] In fact, it was Feuerbach who had accomplished the development of a true materialist philosophy. Through the inversion of Hegel's dialectic, he showed that a true philosophy should take nature not as a mediating stage in the self-development of the Idea, but must have the former as both starting point and endpoint of its theoretical reflection. As Schmidt points out:

> For Feuerbach, Hegel's philosophy is philosophy from the standpoint of the philosopher, while he is a philosopher from the standpoint of non-philosophy. Instead of beginning with philosophy in order to end with philosophy, he wanted to begin with non-philosophy in order to return through philosophy to non-philosophy … The new philosophy no longer claimed any special position as against the other sciences but had its presupposition, like them, in nature.[12]

Yet even though Feuerbach developed his critique of Hegel from the standpoint of 'non-philosophy', he remained a philosopher. Although he did not see his own philosophy as bearing any privilege over the rest of the sciences, insofar as it also had its presupposition in nature,[13] he still saw his intellectual endeavour as a philosophical reflection. In other words, he offered a general – in his case, naturalist – *interpretation of the world* (a 'worldview') that was meant to provide an external 'philosophical' foundation for the materiality (and hence objectivity) of human subjectivity. The human subject (hence thought as her/his corporeal, material attribute) was thus turned into an *object of theoretical contemplation*.

> The new philosophy makes man – with the inclusion of nature as the foundation of man – the unique, universal and highest foundation of philosophy.[14]

[10] Ibid.

[11] Ibid.

[12] Schmidt 1971, p. 24.

[13] Ibid.

[14] Feuerbach 1986, p. 70.

And from that philosophic standpoint, which ultimately still 'regards the theoretical attitude as the only genuinely human attitude',[15] it was impossible for Feuerbach to see the materiality of human thought in its determination as the form in which 'sensuous human activity, practice' is organised.[16]

At this juncture, and in order to clarify the matter further, it is worth delving deeper into my prior, admittedly controversial, claim, namely, that already in the *Paris Manuscripts* and for the rest of his lifetime, Marx's materialist dialectical science entailed the transcendence of *all* philosophy.[17] In other words, the inability of philosophical thought to translate into transformative practical criticism – hence to achieve the real, and not merely formal, unity of 'theory and practice' – is not simply a problem of Feuerbach's contemplative theoreticism, which could be redressed through the development of a materialist 'philosophy of praxis'.[18] According to this latter train of thought, the key issue in Marx's critique of Feuerbach comes down to the substitution of the historically situated productive activity of the human being as the active mediator in the establishment of the unity between humanity and nature for the merely passive unity emphasised by the latter.[19]

---

[15] Marx 1976d, p. 3.

[16] For good analyses of the similarities and differences between Marx and Feuerbach, see Colletti (1973, pp. 222–8; and 1992, pp. 51–6), Schmidt (1971, pp. 24–33) and, especially, Arthur (1986, pp. 114–25). In Spanish, Sánchez Vázquez (2003) provides an insightful discussion of the connection between Marx and Feuerbach, specifically focused on the notion of 'praxis', which also sheds light on the precise reason behind the latter's 'theoreticism'. In my view, he convincingly shows that attempts to downplay their distance such as Mondolfo's (1960) remain unpersuasive.

[17] From a *textual* point of view, as remarked by Korsch in *Marxism and Philosophy* (1970), the claim is uncontroversial after *The German Ideology* and the *Theses on Feuerbach*, where there are numerous remarks in which Marx and Engels explicitly reject philosophy for being inherently uncritical alienated thought. My claim is that this rejection already obtains in the *Paris Manuscripts*. It goes without saying, as Gunn (1989, p. 3) puts it, that this overcoming of the philosophical standpoint does not amount to a relapse into a positivism or scientism uninterested in 'categorial questions'. See footnote 25 below.

[18] The explicit formulation of the idea of Marxism as a 'philosophy of praxis' is usually attributed to Gramsci's critique of the objectivism and scientism of the Marxism of the Second International epitomised in Bukharin's *Manual*. See Sánchez Vázquez 2003, pp. 64–7. More generally, for a study of Gramsci's thought as a whole, see the recent groundbreaking study by Thomas (2009). But, of course, the *philosophical* attempt at a restoration of subjectivity and the problematic of the unity of theory and practice has been the thread guiding all the works of the 'founding fathers' of so-called 'Western Marxism' (Adorno 2007; Korsch 1970; Lukács 1971). In my view, for reasons which will become apparent in what follows, the very fact that the attempt was carried out philosophically, rather than through the further systematic development of the critique of political economy, doomed it to failure.

That this is part and parcel of Marx's critique of Feuerbach is without dispute. But my argument is that the radicality of Marx's break with Feuerbach's philosophy, which in turn leads him to transcend philosophy altogether, cannot be captured if one stops short at that dimension of his critique. For, thus posed, the critique only amounts to a change of the cognitive *object* of philosophical analysis, which nonetheless remains in a materially external relation to transformative conscious life activity itself. In other words, 'historically-determined productive practice' replaces Feuerbach's 'abstract man' as the external object of cognition, but the abstractly and one-sidedly theoretical determination of scientific knowledge is not overcome. Scientific knowledge remains, to borrow Gunn's expression, a *theory of*, that is, a form of cognition that 'construes its object ... as something which stands over against the subject who lays claim to know it',[20] thus reifying its object. In this case, it becomes a *general theory of human practice* as an object of philosophical analysis.[21]

Thus, interpretations of Marx's dialectical science as a philosophy of praxis tend to take as their *point of departure* the construal of a general concept of human productive activity, in order to ground its essential rationality, freedom, transformativity, morality, cognitive objectivity, etc. On that basis, it is then 'applied' *normatively* to assess the potentialities of concretely existing human actions in their singularity. Or, alternatively, theory is instrumentally mobilised to ‘guide’ or ‘inform’ human actions; in particular, revolutionary practice.[22] Either way, theory is rendered a self-subsistent activity which starts from itself and achieves closure within itself and which, only after its abstractly cognitive act reaches completion, is then utilised to guide or judge actually existing transformative actions. Seen in this way, and no matter the declamation of the philosopher of praxis, the connection between theory and practice is bound to remain external.

---

[19] Schmidt 1971, pp. 26–7; Sánchez Vázquez 2003, pp. 123–5, 180.

[20] Gunn 1992, p. 4.

[21] Strictly speaking, Gunn's discussion of scientific knowledge as 'theory of' refers to 'society' rather than to 'practice' as a reified object of cognition. As for his own take on the connection between theory and practice in Marx's thought, Gunn tries to capture it through what he calls theory's practical reflexivity. According to Gunn (1989, pp. 6–7; see also 1987), a theory is practically reflexive when it not only theorises its 'object' but also, in the very same conceptual and totalising movement, self-consciously reflects both on its own practical situatedness (i.e. it inheres in a practical totality or it is an expression or 'moment' of an essentially practical social world) and on the validity of its own categories or truth criteria. Although Gunn (1987, p. 42) claims that this conceptualisation of the relation between theory and practice renders it 'internal', I think it does not transcend all exteriority between them, the latter still remaining a reified object from the point of view of the subject of cognition. Thus, theory reflects on itself while reflecting on practice, but it still subsists as an abstractly theoretical activity. It is 'in unity with' practice but nonetheless remains 'distinct from it' (Gunn 1987, p. 41). See Chapters 6 and 9 below for an elaboration of the further ramifications of this discussion.

By contrast, as Iñigo Carrera insists, Marx’s revolutionary science does not start out by construing a general philosophical concept of praxis, but takes as its starting point the search for an answer to the directly practical question about the conscious organisation of ‘actually existing’ human transformative action in the unity of its determinations.[23] It therefore immediately is, in its generic condition as a historical form of social consciousness, an *inner* moment of the unfolding of human practice itself: the ideal appropriation of nature’s potentialities as the specifically human form of organising their real appropriation in the course of the social life process. This is why Marx remarks in the second *1844 Manuscript* that ‘the idea of one basis for life and another for science is from the very outset a lie’.[24]

In this sense, science as practical criticism does not need to be applied to or guide an externally conceived practice, since it situates itself *within* the field of real human action in its concrete singularity from the very outset. And it does so with the aim of uncovering and *ideally* appropriating human practice’s *immanent* material and social determinations – hence its objective transformative potentialities – in order consciously to regulate their *real* actualisation through ‘revolutionary’, ‘practical-critical’ activity. This, I think, is the only meaningful way in which to materialistically understand the so-called ‘unity of theory and practice’.[25]

---

[22] See Sánchez Vázquez 2003, whose study of the ‘concept of praxis’ in Marx and Marxism is a particularly telling case in point.

[23] Iñigo Carrera 1992, p. 2.

[24] 1992b, p. 355.

[25] Note that in the course of its unfolding, the search for the inner transformative potentialities of concretely existing human action will most certainly have to advance towards more abstract determinations which transcend immediate perception or intuition. Many of them will be forms of the real whose investigation usually falls within the domain of philosophical reflection (epistemological and/or even ontological) and which tend to be deemed ‘metaphysical’ questions by positivistic thought. As a matter of fact, many of the simpler ones have been discovered and expounded by Hegel in his *Science of Logic*, albeit within a mystical shell which comprises a series of redundant categories and formal steps

In brief, Feuerbach cleared the terrain for the necessary step forward in the development of a materialist standpoint. However, it was only Marx who took up this challenge and discovered that the completion of the materialist inversion of Hegel required more than the 'naturalisation' of philosophy. It involved the discovery that the starting point for any true materialist science was not just the 'social relation of man to man' in the abstract, but grasped in its essential determination as historically determined conscious productive practice. Moreover, the latter was not simply seen by Marx as an alternative external object of scientific-philosophical inquiry. Instead, it was the real form which carried, as an immanent necessary moment of its unfold-

---

in the systematic-dialectical exposition. On this issue, see Caligaris and Starosta 2014. In this sense, science as practical criticism does not deny the objectivity of those more abstract determinations of human action. However, it does not approach them *philosophically* (hence as a self-contained external object that constitutes the point of departure of theoretical reflection) but through critical-practical dialectics. It thereby discovers them analytically as *immanent* in concretely existing human transformative practice itself in the very process of its conscious organisation (I shall return to the specific determination of the moment of analysis in the dialectical method in the next chapter). In other words, those more abstract determinations constitute an inner content which is carried by human action itself, the latter being their most concrete or complex mode of existence. To make the point differently, in the same vein as many Marxists acknowledge that Marx's dialectical investigation of the same capitalist social forms which political economy represents ideologically does not turn the former into an 'economic theory' but is a *critique of political economy*, the inquiry into more abstract determinations of the real which are usually the object of philosophical representation does not turn the Marxian scientific endeavour into a philosophy but represents a *critique* of it. In *Marxism and Philosophy*, Korsch (1970) poses the problematic quite sharply, but, presumably as an overreaction to the hostility to 'philosophical questions' in the positivistic Marxism of the Second International, did not dare making the next step involved in the transcendence of the standpoint of philosophy. Thus, he speaks of (and actually vindicates) the 'philosophical content' of Marxism and still sees the 'revolutionary materialist dialectic' as the 'philosophy of the working class', albeit one which aims at its self-abolition through the overthrow of bourgeois society as a whole. See Korsch 1970, p. 97. The same tension runs through Adorno's *Negative Dialectics* from the very opening lines of the Introduction: 'Philosophy, which now seems obsolete, lives on because the moment to realize it was missed' (Adorno 2007, p. 3). This hesitant attitude of Adorno's towards the status of Marxian practical-critical dialectics vis-à-vis philosophical thought has been carried over by his contemporary disciples who took up his methodological research programme to develop a critical reconstruction of the critique of political economy. Thus Backhaus (1992, p. 55) locates the latter 'in-between philosophy and science', since economic concepts are not simply economic but philosophical.

ing, the rational comprehension of its own inner determinations i.e. revolutionary theory. It was in the very nature of Feuerbach's philosophy, and *a fortiori* of *all* philosophical thought, to be incapable of grasping this elementary determination of human subjectivity. The development of a materialist science, as the comprehension – and hence conscious organisation – of concretely existing human transformative practice, entailed the overcoming of philosophy.

Hegel and the 'Dilemma of Epistemology'

The central question of modern philosophy is, to put it simply, an epistemological one, in the sense of being an enquiry into the conditions for the genesis and attainment of true scientific knowledge. As Gunn puts it, modern philosophy is essentially a 'metatheory', a 'second-order discourse' aiming at evaluating and validating the categories employed by scientific theory, conceived as 'first-order discourse'.[26] More concretely, philosophy is meant to offer, in the manner of an external arbiter, the criteria against which we might attribute 'objective validity' to the representations produced by scientific theory. This means, therefore, that the objectivity of scientific knowledge is considered to be extrinsically grounded in the generic *subjectivity* of an abstractly rational and free-thinking human being.[27] The difficulties of epistemology arise because of its attempt to provide, through an act of cognition, a foundation for the conditions under which a valid act of cognition can take place.[28] From this starting point, two possible paths seem necessarily to follow. Either the formulation of a further external arbiter which could validate the procedures of the epistemological cognitive act itself, which would in turn be in need of external grounding; or the dogmatic utilisation of those very same criteria with which it attempts to found the original act of knowledge, in order to account for the objectivity of its own activity. Epistemology's own claims to truth seem to fall into the trap of either circularity or infinite regress.[29] Faced with this dilemma, Kant ended up claiming that the only way out is to humbly recognise the limits of true human knowledge which thus becomes restricted to the phenomenal world, leaving the 'thing-in-itself' as an unreachable content for the act of cognition.[30]

[26] Gunn 1989, p. 89.

[27] Iñigo Carrera 2008, p. 253.

[28] Colletti 1973, p. 199.

[29] Gunn 1989, pp. 89–90; Arthur 1986, p. 50.

[30] Williams 1989, pp. 32–8.

With his characteristic sarcastic tone, in the Introduction to the *Encyclopaedia*, Hegel summarises very clearly the oxymoron that self-conscious traditional epistemology (which he saw in what he calls 'critical philosophy') had set for itself:

> One of the main points of view in the *Critical* Philosophy is the following: before we embark upon the cognition of God, or of the essence of things, etc., we should first investigate our *faculty of cognition* itself, to see whether it is capable of achieving this. We should first get to know about the *instrument*, before undertaking the task that is supposed to be accomplished by means of it; for, otherwise, if the instrument is inadequate, then all further effort would have been expended in vain … But the investigation of cognition cannot take place in any other way than cognitively; in the case of this so-called tool, the 'investigation' of it means nothing but the cognition of it. But to want to have cognition *before* we have any is as absurd as the wise resolve of Scholasticus to learn to swim before he ventured into the water.[31]

This point was also made by Hegel in the Introduction to the *Science of Logic*. There he remarked on the specific nature of the science which had thought as its own particular content. For the rest of the sciences, method and subject matter are distinguished so that they are

> permitted to speak of their ground and its context and also of their method, only as premises taken for granted which, as forms of definitions and such-like presupposed as familiar and accepted, are to be applied straight-way, and also to employ the usual kind of reasoning for the establishment of their general concepts and fundamental determinations.[32]

However, since logic has those laws of thinking themselves as its own content, it cannot presuppose them but needs to discover them in the course of its development. This does not mean that no justification for the objectivity of pure thinking is needed. But this justification is not to be part of the science of pure thought itself but the presupposition of its beginning. Hegel had given this deduction, which is nothing more than the movement of consciousness until discovering the objectivity of its own cognising activity, in the *Phenomenology of Spirit*.[33]

---

[31] Hegel 1991, p. 34.

[32] Hegel 1999, p. 43.

The point is that the whole problematic arises because epistemology starts from the radical *separation* between knowledge and reality, or subject and object of cognition. Hegel's alleged solution was then to solve those contradictions by going right to their essential source in that deficient starting point of traditional epistemology. The general result of his *Phenomenology of Spirit* is precisely the ontological *identity* between thought and being.[34] This is the essential content of absolute knowledge as the self-knowledge of absolute spirit's own dialectic. Certainly, Hegel does not extrinsically *confront* this essential truth with the allegedly wrong starting point of traditional epistemology in order to replace it with his own, more satisfactory account. This would leave him with exactly the same dilemma that traditional epistemology faced. The whole gist of his phenomenological method consists precisely in taking what he calls the standpoint of consciousness (i.e. that which sees a radical separation between consciousness and its object) as the starting point for his science of the experience of consciousness (that is Hegel's definition of phenomenology). More precisely, he starts from the simplest figure of that knowing subjectivity, i.e. immediate certainty. From this beginning, and through a method of *immanent critique*, Hegel attempts to show that his own absolute knowledge is a necessary concrete form into which that simple initial figure of the knowing consciousness develops.[35] The phenomenology is the laborious odyssey of consciousness passing through all of its defective figures until reaching its plenitude as absolute knowledge. The crucial thing is that this development is not the product of the failure of the different forms of consciousness to measure up to some external yardstick provided by the philosopher, the alleged bearer of absolute truth. On the contrary, this motion is generated by the contradictions produced by each figure of consciousness itself when measured against its own standards. Although at first there seems to be a perfect identity between what consciousness takes to be the object in itself and the way it knows the object (i.e. the object for consciousness), closer scrutiny of each figure's cognising experience reveals that those two moments are actually in opposition. It is the development of its own contradictions that pushes consciousness forward to ever newer, more complex forms until reaching the stage of absolute knowing. In this sense, it is a process of philosophical self-education of ordinary consciousness. The philosopher does not teach ordinary consciousness the content of absolute knowing (the identity of thought and being), but just describes the self-movement of the latter through which it eventually grasps that essential truth by itself. The false is then revealed to be not simply 'wrong', but a partial view that results from the fixation and absolutisation of what actually is a determinate moment or appearance of a more comprehensive, concrete totality, namely, absolute spirit's self-development.[36] At the end of the journey, consciousness thus learns that the opposition and dichotomy between subjectivity and objectivity was posited by consciousness itself.

---

[33] Hegel 1999, p. 49.

[34] Houlgate 2001 and 1998.

[35] On immanent critique in Hegel, see Hyppolite 1991.

> Spirit, therefore, having won the Notion, displays its existence and movement in this ether of its life and its *Science* … Whereas in the phenomenology of Spirit each moment is the difference between knowledge and Truth, and is the movement in which that difference is cancelled, Science on the other hand does not contain this difference and the cancelling of it. On the contrary, since the moment has the form of the Notion, it unites the objective form of Truth and of the knowing Self in an immediate unity.[37]

In this way, absolute knowing reveals that the externality between form and matter of cognition is an appearance that vanishes as soon as one comes to adopt its standpoint. Thus, according to Hegel, the problem of traditional epistemology is solved. The determinations of thought are not pure subjective forms that organise a given content but the immanent essential determination of everything that exists when grasped in its universality, that is, in the objectivity of its 'logical element'. Liberated from 'the opposition of consciousness', pure thinking recognises its own objectivity as the Notion, i.e. as

> the nature, the peculiar essence, that which is genuinely permanent and substantial in the complexity and contingency of appearance and fleeting manifestation … the notion of the thing, the immanent universal … the very heart of things, their simple life-pulse, even of subjective thinking of them.[38]

---

[36] Hegel 1977, pp. 490–1.

[37] Hegel 1977, p. 491.

[38] Hegel 1999, pp. 36–7.

On this basis, logic is thus free to proceed with the presentation of the self-determining movement of the Notion by showing the multiplicity of different thought forms that structure being in all its complexity. However, after the reconstruction of the experience of consciousness in the *Phenomenology of Spirit* it becomes evident for philosophy that this exposition of objective pure thinking cannot consist in the mere external 'aggregate of definitions and propositions which ordinarily passes for logic'.[39] This collection of external relations among the different thought forms is, according to Hegel, the picture philosophy gets when it wrongly borrows its scientific method from the science of 'the quantitative aspects of the determinations', i.e. mathematics.[40] Quite to the contrary, Hegel argues, in the *Phenomenology of Spirit* he had already shown the workings of the 'scientifically correct method' as the ideal reproduction of the 'inner self-movement' of the object of cognition, which is governed by the 'dialectic which it possesses within itself'.[41] That is, science must proceed by following 'the inner negativity of the determinations as their self-moving soul':[42]

> All that is necessary to achieve scientific progress – and it is essential to strive to gain this quite simple insight – is the recognition of the logical principle that the negative is just as much positive, or that what is self-contradictory does not resolve itself into a nullity, into abstract nothingness, but essentially only into the negation of its particular content, in other words, that such a negation is not all and every negation but the negation of a specific subject matter which resolves itself, and consequently is a specific negation, and therefore the result essentially contains that from which it results; which strictly speaking is a tautology, for otherwise it would be an immediacy, not a result. Because the result, the negation, is a specific negation, it has content. It is a fresh Notion but higher and richer than its predecessor; for it is richer by the negation or opposite of the latter, therefore contains it, but also something more, and is the unity of itself and its opposite. It is in this way that the system of Notions as such has to be formed – and has to complete itself in a purely continuous course in which nothing extraneous is introduced.[43]

[39] Hegel 1999, p. 51.

[40] Hegel 1999, p. 52.

[41] Hegel 1999, p. 54; see also 1977, pp. 31–2.

[42] Hegel 1999, p. 56.

[43] Hegel 1999, p. 54.

Thus Hegel distinguishes between what he terms the 'understanding' and 'speculative thought'. The former grasps thoughts as self-subsistent entities or immediate affirmations:

> Thinking as *understanding* stops short at the fixed determinacy and its distinctness vis-à-vis other determinacies; such a restricted abstraction counts for the understanding as one that subsists on its own account, and simply is.[44]

Moreover, and this is what distinguishes understanding from mere 'representation', on that basis it attempts to establish

> a necessary relation between the isolated determinations of representation – whereas representation leaves them *side by side*, in its undetermined space, linked only by the simple 'and'.[45]

However, unwilling to recognise that 'according to its proper determinacy ... the dialectic', or negativity, 'is the genuine nature that properly belongs to the determinations of the understanding, to things, and to the finite in general',[46] the understanding can only end up establishing a connection among all those conceptions by means of purely *subjective* reflection, that is, by following a necessity which is *external* to the immanent determination of the object of cognition at stake.

Conversely, speculative thought involves the consciousness both of the 'dialectical moment' present in all 'things [as they are] in and for themselves',[47] and also of 'the affirmative that is contained in their dissolution and in their transition'.[48] It therefore discovers in the dialectic 'the moving soul of scientific progression ... the principle through which alone *immanent coherence and necessity* enter into the content of science'.[49] Speculative science thus grasps the relations among things in their objective, immanent necessity.

In this way, Hegel claims to have moved beyond the antinomies of philosophical thought. He sees himself as not only overcoming the externality between the form and content of knowledge, but also as discovering in the dialectic the form in which the universality of the Notion moves, thus giving life and motion to every particular real form, whether natural or 'spiritual'. Thus seen, logic 'no longer stands as a particular alongside other particulars, but includes them all within its grasp and is their essence, the absolutely True'.[50]

[49] Hegel 1991, p. 128.

It is with these conclusions, according to Marx, that far from solving the dilemma of epistemology, Hegel carried the idealist inversion intrinsic to all philosophical thought to its limit. And this is so in a two-fold sense. Negatively, he thereby unwittingly exposed the source of the idealist inversion inherent in philosophy in the replacement of the movement of the real, i.e. its determinate immanent necessity, with a *logical necessity*. The content of the materialist inversion needed thus became clear, namely, the overcoming of all forms of *logical representation* of reality through the discovery of the *specific* necessity immanent in the *determinate* object of cognition (and hence of transformation) at stake, that is, through the 'reproduction of the concrete by means of thought'.[51] Positively, in discovering contradiction as the 'negativity which is the indwelling pulsation of self-movement and spontaneous activity'[52] of every existing real form, Hegel grasped the dialectic as the *form* of cognition (i.e. the method) capable of expressing the aforementioned 'inner necessity controlling the object' to be known. *With these two insights in their unity*, Marx would begin his positive development of science determined as a necessary concrete moment of the revolutionary transformation of society into the free association of individuals.[53]

---

[50] Hegel 1999, p. 59.

[51] Following Iñigo Carrera (2008), I shall use the expressions 'logical representation' or 'representational thought' to refer to the form of scientific or philosophical cognition that moves according to a purely ideal necessity, external to the real forms to be known. By the 'reproduction of the concrete by means of thought' or, simply, 'dialectical knowledge', I mean that form of science which grasps the necessity for self-transformation immanent in things themselves. They correspond to what Hegel called 'understanding' and 'speculative thought', respectively, minus his idealist inversion.

[52] Hegel 1999, p. 442.

[53] The reduction of the materialist inversion of Hegel to the latter insight only, generally coupled with the dogmatic claim that the subject of the movement described by Hegel's *Logic* is not the 'Idea' but 'Matter', does not move an iota beyond logical representation. It just formally changes an idealist dialectical logic into a 'materialist' one, to be extrinsically applied to every determinate concrete form of material reality. This kind of reading of the 'Hegel-Marx connection' is broadly contained in the orthodox views of *Diamat* as epitomised in Stalin (1947) and official Soviet manuals, which in turn drew direct inspiration from the classical works of Engels (1987 and 1991), Plekhanov (1965), and Lenin (1961). In the founding works of *Diamat*, the *Logic* is usually taken as containing 'the

Marx's Critique of Hegel's Philosophy in the *Paris Manuscripts*

Even among the most lucid commentaries on Marx's *Paris Manuscripts*, the section on the critique of the Hegelian dialectic is read primarily as an attempt to develop a materialist inversion of Hegel's *Phenomenology of Spirit*. In this sense, Arthur's detailed commentary is a case in point.[54] According to this author, the essence of Marx's criticism consists in the inversion of Hegel's historical dialectic through the replacement of 'his Bildungsroman of spirit with that of man'.[55] Thus Marx is seen as part of the Young Hegelian tradition of critical appropriation of Hegel's thought. This involves the recognition that Hegel's dialectic expresses truth but in mystified form. Feuerbach's influence in particular consisted in that attempt to refer all in Hegel that belongs to that abstraction called 'Spirit' to real man as an objective, natural being. However, the argument goes, against the passivity and ahistoricity of Feuerbach's views about the human being, Marx recovered the 'active', productive and historical side contained in the Hegelian dialectic. Hence the latter's positive aspect of the 'dialectic of negativity as the producing principle'.[56] The self-development of Spirit through alienation and its overcoming is actually a mystified representation of the human being's self-production through labour.[57] The essential difference between Marx's and Hegel's accounts thereby lies in the concrete subject of the dialectic of negativity. Whilst for Hegel the subject of this activity is an abstraction called consciousness, for Marx, building on Feuerbach's criticism, it is the 'real, corporeal *man*, his feet firmly planted on the solid earth, and breathing all the powers of nature'.[58] In turn, this question would revolve around the difference in political stances towards capitalist society between Hegel and Marx. For the former, the overcoming of alienation does not involve

---

fundamental laws of dialectics', which are then to be applied to more concrete objects such as history, capitalism, and so on. It is thus argued that Hegel would have discovered those laws, but 'in his idealist fashion as mere laws of thought' (Engels 1987, p. 356). This position is nicely expressed by Lenin's famous aphorism in his *Philosophical Notebooks*: the question is to 'read Hegel materialistically … that is to say … cast aside for the most part God, the Absolute, the Pure Idea, etc.' (Lenin 1961, p. 104). A more thorough critical discussion of this orthodox perspective in connection with contemporary 'systematic dialectical' approaches can be found in Caligaris and Starosta (2014).

[54] But see also Marcus 1980, pp. 82–3.

[55] Arthur 1986, p. 56.

[56] Marx 1992b, pp. 385–6.

[58] Marx 1992b, p. 389.

the practical, real abolition of an alienated social world but only a change in the attitude of consciousness regarding those forms of objectivity.[59] In brief, in this reading, the primary aspect of Marx's criticism of Hegel in the *Paris Manuscripts* concerns the question of the idealist character of the Hegelian dialectic of human consciousness. Moreover, this critique would have served Marx as a way of developing the central insight of his 'social ontology', namely, the essentiality of *productive activity* in the historical development of human beings.

Although the relevance that this question about the idealism of Hegel's *Phenomenology of Spirit* had for Marx's development *in those years* is beyond dispute, I think that a more fruitful reading strategy should focus not on the critique of that 1807 text, but on Marx's confrontation with Hegel's *Logic*. And there are mainly two reasons for this. First, as was already discussed, although the question of productive subjectivity and its historical forms remained an essential element of Marx's materialist standpoint, the general dialectic of negativity as the foundation for the overcoming of alienated labour was left behind in his later works. Secondly, that one-sided emphasis on the discussion of the *Phenomenology of Spirit* overlooks the fact that Marx's concern for that early text is subordinate to his critique of the *Science of Logic* as the consummation of Hegel's hypostasis of logic's ideal necessity.[60] Hence, according to our reading the significance of those pages for Marx's subsequent intellectual development is not so much 'socio-ontological' as *methodological*.

---

[59] Although I cannot address the question here, I would like to acknowledge the existence of a debate over the fairness of Marx's critique of Hegel. Thus Rose (1995, pp. 214–15) has challenged Marx's reading of Hegel for being essentially Fichtean (see Arthur 1986, pp. 74–6, for a reply to Rose; and Smith 1990b for a critique of Arthur). Other authors have also criticised Marx for not realising that, actually, there is no difference between Hegel's dialectic and his own (Fraser 1998, pp. 34–6). Fine (2001, Chapter 5) also argues that Marx failed to recognise the methodological affinity between his dialectical method and Hegel's. But, in addition, he explores the consequences of the misreading of Hegel for Marx's own thought. Be that as it may, the relevant point for this book is not whether Marx was right or wrong in his reading of Hegel, but the positive methodological insights developed *through* the critique of the latter.

[60] The only commentator I am aware of who adopts this reading strategy of that section of the *Manuscripts* is Murray (1988, pp. 46–7). However, he does not develop this in the methodological direction of the distinction between representational thought and dialectics. Instead, he uses it to put forward his own variant of the 'homology thesis', which sees a parallel between Hegel's logical concept and capital, inasmuch as they are both hypostasised abstractions indifferent to any qualitative distinction. On the 'homology thesis', see the debate between Chris Arthur (2003a and 2003b) – supporter of a strong version of the thesis, whereby the parallel between the Idea and Capital is not just general but applies to almost every single category – and Tony Smith (2001 and 2003) – for

Certainly, Marx's initial entry point for the discussion of Hegel is the latter's abstract dialectic of absolute spirit with its allegedly conservative result. After praising Feuerbach for positing nature and the human being – 'the self-sustaining positive' – as the starting points of his philosophy, he goes on to argue that it is for exactly the opposite reason that Hegel's dialectic is to be criticised. However, this critique should recognise that, albeit in an idealist form, Hegel had unconsciously discovered the general form of motion of the historical process through which the human being is produced. According to Marx,

> Hegel has merely discovered the *abstract, logical, speculative* expression of the movement of history. This movement of history is not yet the *real* history of man as a given subject, it is simply the process of his *creation*, the *history of his emergence*.[61]

While in the conventional reading this quotation is read with an emphasis on Hegel's finding of the form of the 'movement of history', I think that, conversely, the crux of the matter resides in Marx's emphasis on the 'abstract, logical, speculative' nature of Hegel's account. Thus Marx's praise of Hegel's discovery of the dialectic of negativity as the 'producing principle' should be qualified. The latter not only served Marx to reveal its material content in the dialectic of labour's self-alienation, but also gave a clear illustration of Hegel's speculative transformation of logic into the source of all movement and life. This is a crucial point. It exposes the procedure of philosophical representation consisting in the substitution of a mental, logical necessity for the real one. Instead of following the real movement of humanity's historical self-development and then discovering that, as far as its form is concerned, it moves according to a dialectic of negativity, Hegel sees the movement of real history only as an(other) instantiation of the logical principle of pure negativity.

---

whom the thesis does not withstand close scrutiny. Another proponent of the mapping of Hegel's logical categories onto Marx's critique of political economy is Meany (2002), although he does it in relation to the *Grundrisse*. More recently, the examination of the homology thesis has been resumed in some of the articles in Moseley and Smith (2014). See, in particular, Smith 2014; Bellofiore 2014; Arthur 2014; Caligaris and Starosta 2014.

[61] Marx 1992b, p. 382.

> Since this so-called negativity is nothing more than the *abstract, empty* form of that real living act, its content can only be a *formal* content, created by abstraction from all content. Consequently there are general, abstract *forms of abstraction* which fit every content and are therefore indifferent to all content; forms of thought and logical categories torn away from *real* mind and *real* nature.[62]

This passage shows with utmost clarity the point which Marx is getting at and of which the discussion of the *Phenomenology of Spirit* constitutes a prelude, namely, the alienated nature of philosophy. That is why Marx wants to take stock of Hegel's philosophy in its entirety, which, inasmuch as he sees it as the most developed form of philosophical consciousness, entails a critique of philosophy *tout court*. In this sense, as Murray points out, Marx's 'concern for Hegel's *Phenomenology* must be understood in terms of the attention to his logic [of absolute idealism]'.[63] As Marx makes clear right at the beginning of that section of the *Manuscripts*, the critique of Hegel should aim at his philosophical *system* as a whole, as presented in the *Encyclopaedia*, since it is that work which condenses the essence of philosophical thought as alienated thought thinking itself.

> Hegel's *Encyclopaedia* begins with logic, with *pure speculative thought*, and ends with *absolute knowledge*, with the self-conscious, self-comprehending philosophical or absolute mind, i.e. superhuman, abstract mind. In the same way, the whole of the *Encyclopaedia* is nothing but the *extended being* of philosophical mind, its self-objectification; and the philosophical mind is nothing but the estranged mind of the world thinking within its self-estrangement, i.e. conceiving itself abstractly.[64]

On the other hand, it is to be remembered that Hegel's *Phenomenology* is not part of his *system* but constitutes its *introduction*.[65] This is why Marx states that the critique of Hegel's philosophy as a whole must *begin* with his *Phenomenology*, which is 'the true birthplace and secret of the Hegelian philosophy'.[66] Hegel considers the *Phenomenology* the work that leads consciousness from its immediate mode of existence to the essential determination of absolute knowledge in the identity of thought and being. In this way, consciousness recognises that its thought determinations are not something different from the determinations of objects existing independently 'out there', but that its own thinking about itself *is* the thinking about the determinations of being. In the words of a Hegel scholar,

---

[62] Marx 1992b, pp. 396–7.

[63] Murray 1988, p. 46.

[64] Marx 1992b, p. 383.

[65] Houlgate 2003, pp. 368–70.

[66] Marx 1992b, p. 383, my emphasis.

> What consciousness comes to understand at the end of the *Phenomenology*, therefore, is the Kantian idea that the determinations of being are in fact the determinations of consciousness, together with the un-Kantian idea that the determinations of consciousness are the determinations of *being*.[67]

Only once consciousness has gone through that journey that lands it on the realm of absolute knowledge can proper philosophy actually begin by reconstituting the path from the abstract determinations of being to its most concrete forms of existence as Spirit. To put it differently, abstractly considered, a consciousness that, for whatever reason, does not hesitate a second about the identity between thought and being could easily skip the phenomenological experience and move straight to the starting point of the system of philosophy which begins with the *Logic*.[68] Hence Marx's critique of Hegel's false starting point with an abstract consciousness, the philosophical representation of the real, corporeal human individual (a point already made by Feuerbach) in her/his historical social relations (the specifically Marxian point). Because that possibility demonstrates that far from moving from the sensuous concrete to the abstract, Hegel's philosophical standpoint never abandoned the realm of abstraction. The alienated essence of philosophy is precisely exposed by its systemic starting point with logic, the science of pure thinking. In particular, the idealist inversion appears with full force in the problematic of the transition from the logical idea to nature. The autonomisation of thought forms from nature and consciousness in the form of pure logical categories and their further integration as moments of the logical Idea reaches its moment of truth when faced with its self-determination as its 'other'. Here Marx resorts to a Feuerbachian line of criticism. Indeed, Feuerbach's characterisation of Hegel as an 'abstract realist' in the *Principles for the Philosophy of the Future* speaks precisely to this problematic:

---

[67] Houlgate 2001, p. 135.

[68] Houlgate 2003, p. 368.

> The statement that only the 'concrete' notion that carries the nature of the real in itself is the true notion expresses the recognition of the truth of concreteness or reality.[69]

The difficulties of that transition betray the absoluteness of Hegel's Idea and actually constitute a proof that abstract, presuppositionless thought is nothing without nature.

> Hegel's positive achievement in his speculative logic is to present *determinate concepts*, the universal *fixed thought forms* in their independence of nature and mind, as a necessary result of the universal estrangement of human existence, and thus also of human thought, and to comprehend them as moments in the process of abstraction … But the abstraction which comprehends itself as abstraction knows itself to be nothing: it must relinquish itself, the abstraction, and so it arrives at something which is its exact opposite, *nature*. Hence the whole of the *Logic* is proof of the fact that abstract thought is nothing for itself, that the absolute idea is nothing for itself and that only *nature* is something.[70]

What makes this metaphysical transition from the idea to nature necessary is precisely the fact that during the whole movement of the idea in its purity (the *Logic*) no particular, determinate content was touched upon. Only the general, the logical, the essentialities or thought determinations were developed, which, because of their generality, are said to structure all forms of the real. But the abstraction reached in this form cannot but long for a particular content, otherwise abstract thought would keep revolving around itself. And this would mean the recognition of its non-absolute character, since its other (nature) would persist in its independence and 'otherness'. Hence the need to bring nature in. However, says Marx, alienated thought can only acknowledge nature as a thought entity. Its existence is the last logical necessity of the absolute idea in its purity, which, to demonstrate its absoluteness, has to self-posit itself in the form of externality, i.e. as nature.

> [T]his whole idea, which conducts itself in such a strange and baroque fashion, and which has caused the Hegelians such terrible headaches, is purely and simply *abstraction*, i.e. the abstract thinker; abstraction which,

---

[69] Feuerbach 1986, p. 48.

[70] Marx 1992b, p. 397.

> taught by experience and enlightened as to its own truth, resolves under various conditions – themselves false and still abstract – to *relinquish itself* and to establish its other-being, the particular, the determinate, in place of its self-pervasion [*Beisichsein*], non-being, universality and indeterminateness; to let *nature*, which it concealed within itself only as a mere abstraction, as a thing of thought, *issue freely from itself*, i.e. to abandon abstraction and to take a look at nature, which exists *free* from abstraction.[71]

The philosopher, who, as 'pure' thinker, sees her/himself as the ultimate incarnation of the human, is actually the ultimate incarnation of the alienated existence of the human. Inasmuch as she/he sees her/his own species-being (that is, her/his specific determination as a labouring natural being) as the very negation of true humanity,[72] she/he can separate thought from the concrete, real thinking human and consider it as the attribute of an abstractly pure thinking subjectivity. Thought forms are thus transformed into categories of pure thinking, which moves according to its own mental necessity and is therefore indifferent to every natural (and hence human) determination. In other words, thought forms are turned into *logical categories* and their movement into logic. In this abstract universality, thought forms are thus seen to express the ideal necessity of reason in its purity, uncontaminated by the contingency of particular contents. While different philosophers tended to privilege this or that group of pure thought forms as the essential logical categories, Hegel synthesised them all in his *Logic* as the science of pure abstraction. This is one of the ways in which, according to Marx, Hegel represented the ultimate expression of philosophical thought. But additionally, as I have already noted, Hegel pushed the idealist inversion to a complacent self-awareness and hence to its plenitude. Certainly in a mystified form, philosophers before Hegel had still preserved some link between thought and the human being. To be more precise, an alienated, abstract representation of the human being as a purely thinking subject. But Hegel went one step further and completed the severance of thought from the human subject, the result of which could only be their reunion in an inverted form, that is, with the process of thought turned into an independent subject itself.[73]

---

[71] Marx 1992b, pp. 397–8.

[72] Fracchia 1991, pp. 155–7.

[73] Marx 1976g, p. 102.

> The man estranged from himself is also the thinker estranged from his *essence*, i.e. from his natural and human essence. His thoughts are therefore fixed phantoms existing outside nature and man. In his *Logic* Hegel has locked up all these phantoms.[74]

And in a footnote, Marx adds:

> We shall see later why Hegel separates thought from the *subject*; but it is already clear that if man is not human, then the expression of his essential nature cannot be human, and therefore that thought itself could not be conceived as an expression of man's being, of man as a human and natural subject, with eyes, ears, etc., living in society, in the world and in nature.[75]

It is the difficult and painful transition from pure thought to nature (difficult for the abstract thinker, that is) that exposes the speculative trick. Because now all the logical categories repeat themselves in the movement of nature, that is, not in their purity, but in the form of externality. Hence, the philosopher involuntarily reveals that those abstract logical categories which she sees herself as engendering by herself through her pure thinking activity, are in fact specific determinations of nature (matter), which she had abstracted from the latter and, by giving them the form of an abstract universality, transformed them into pure thought forms. The subsequent necessary return to nature can only produce an inverted image of nature, that is, as a dead materiality which has life, movement and meaning only as a mode of existence of the logical concept. In other words, the philosopher deals not with real nature, but with a thought entity.

> But *nature* too, taken abstractly, for itself, and fixed in its separation from man, is *nothing* for man. It goes without saying that the abstract thinker who decides on intuition, intuits nature abstractly. Just as nature lay enclosed in the thinker in a shape which even to him was shrouded and mysterious, as an absolute idea, a thing of thought, so what he allowed to come forth from himself was simply this *abstract nature*, nature as a thing of thought – but with the significance now of being the other-being of thought, real, intuited nature as distinct from abstract thought. Or, to put it in human terms, the abstract thinker discovers from intuiting nature

---

[74] Marx 1992b, p. 398.

[75] Marx 1992b, p. 389.

> that the entities which he imagined he was creating out of nothing, out of pure abstraction, in a divine dialectic, as the pure products of the labour of thought living and moving within itself and never looking out into reality, are nothing more than *abstractions* from *natural forms*. The whole of nature only repeats to him in a sensuous, external form the abstractions of logic.[76]

Marx's critique of Hegel's *Logic* in the final section of the *Manuscripts*, and especially the transition from the Logical Idea to Nature, is crucial to grasp Marx's revolution in the mode of science. In effect, in the course of his engagement with Hegel he becomes aware of the source of the idealist inversion of which all representational thought suffers for being condemned to remain a concrete form of the reproduction of capital (i.e. uncritical alienated thought). And the key to this critique does not simply reside, as *Diamat* would have it, in the fact that Hegel sees the Idea as the subject of the dialectic, so that the inversion would consist in leaving his dialectic intact and dogmatically claiming that the subject is nature or matter. There is no doubt that all that exists (human thought included) is a more or less developed concrete form of matter, resulting from the latter's self-movement through a process of differentiation, that is, through the self-production of qualitative differences. The only alternative to this would be a creationist view. Now from a communist perspective, that point, however valid, is a self-evident truism. Already in Marx's time, the atheist standpoint was well established in the communist movement, so that, as he states in the *Manuscripts*, it already constituted a basic presupposition of revolutionary science.

> Atheism, which is the denial of this unreality, no longer has any meaning, for atheism is a *negation of God*, through which negation it asserts *the existence of man* through this negation. But socialism as such no longer needs such mediation.[77]

But as this passage also makes clear, proletarian science does not come down to atheism. Or, more precisely, the revolutionary science of the working class does not even need such mediation, since 'its starting point is the *theoretically and practically sensuous consciousness* of man and of nature as *essential beings*'.[78]

---

[76] Marx 1992b, pp. 398–9.

[77] Marx 1992b, p. 357.

[78] Ibid.

Hence, the *philosophical* quarrels within Soviet Marxism over the question of the primacy of thought or matter in the process of knowledge, which is nothing but the disguised secular form of the classical theological question,[79] were not only scholastic but peculiarly anachronistic ones. As an expression of the backward nature of the Russian process of capital accumulation, those essentially ideological forms could not, as German criticism in Marx's time, but 'be preoccupied with the old world'.[80] Later, when the Stalinist regime completed the dogmatic codification of Marx's revolutionary science through its conversion into an official state ideology, that anachronistic emphasis on the materialist *philosophical worldview* as the distinguishing mark of proletarian science was taken even further. That distinction was used to legitimise the use of state violence against those who personified working class resistance to that absolutely centralised process of exploitation.

Coming back to my point: the importance of Marx's critique of Hegel's *Logic* in the *Paris Manuscripts* does not consist in opposing a materialist philosophy to Hegel's absolute idealism. The crux of the matter resides in the fact that through the critique of Hegel, Marx got to grips with the essential difference between representational thought, as the uncritical form of alienated consciousness, and the reproduction of the concrete by means of thought as the form of revolutionary science. Hegel's *Logic* exposed without ambiguity the source of the idealist inversion present in logical representation in all its expressions, whether scientific or philosophical. In a sense, the distinction between the idealist and the materialist standpoints was relevant for Marx. However, it did not pertain to two different 'philosophical outlooks', but was embodied in the very form of the process of cognition, in the mode of scientific knowledge. The point Marx is making is that the idealism of logical representation springs from its replacement of the determinate movement of nature and history with a mental construction, structured on the basis of a logical necessity. The latter, by its own nature as a subjective reflection, can only remain external to the particular natural or social forms at stake. Behind the need to provide an external mental necessity to put real forms into 'theoretical relation' rests the assumption that those forms are incapable of establishing relations by themselves. In other words, that those forms are lifeless abstractions which therefore do not embody any qualitative potentiality or determinacy whose realisation involves its self-transformation into another, more concrete form. As already mentioned, this is what Hegel discovered as the flawed procedure of what he called the 'understanding', which represented real forms as a universe of indifferent and self-subsistent entities. Devoid of any immanent necessity driving them to self-movement, real forms can only be put into *external* relation by means of subjective reflection. Against this view, Hegel opposed the reproduction of the immanent movement of real forms or dialectical cognition as the scientifically correct method. However, for Hegel this did not involve the transcendence of logical thought. On the contrary, it involved the elevation of logic, the science of pure thinking, to the status of *the* science *par excellence*. For although he claimed the correct form of science to be the reproduction of the 'inner life' of the determinate object of cognition, the original source of that movement did not lie in those particular real forms themselves but *in their determination as concrete modes of existence of pure logical thought forms*. The latter are the ones that posit life into what would otherwise be lacking in meaning and inner movement. In the words of Marx,

---

[79] Marx 1992b, p. 381.

[80] Marx 1992b, p. 379; see also Pannekoek 1938, Chapter 7.

> In the natural form, superseded Movement as Matter corresponds to superseded Becoming as Being. Light is the *natural* form of *Reflection-in-itself*. Body as *Moon* and *Comet* is the *natural* form of the *antithesis* which, according to the *Logic*, is *the positive grounded on itself* and the *negative* grounded upon itself. The Earth is the *natural* form of the logical *ground*, as the negative unity of the antithesis, etc.
>
> *Nature as nature*, i.e. insofar as it is sensuously distinct from the secret sense hidden within it, nature separated and distinct from these abstractions is *nothing*, a *nothing proving itself to be nothing*, it is *devoid of sense*, or only has the sense of an externality to be superseded.[81]

In discussing Hegel, the issue at stake for Marx was not the philosophical question of whether matter determined thought or vice versa, but the distinction between logic, which was 'completely indifferent to all real determinateness',[82] and the reproduction in thought of that 'real determinateness' as it unfolds in nature and history.[83] And here it is important to point to a subtle but crucial difference between the critique of Hegel's *Logic* in the *Paris Manuscripts* and in the *Critique of Hegel's Philosophy of Right*. At first sight, they seem to come down to the same essential point. According to Marx, whether in the case of nature or the state, Hegel inverts their specific movement as an instantiation of the logical movement of the concept. Whilst this is true enough as far as the negative view of Hegel's idealistic inversion is concerned, this similarity of the critique between the two texts overlooks their difference regarding Marx's positive view on what was to replace Hegel's 'applied metaphysics'. Indeed, there is a substantial leap in the *Paris Manuscripts* compared with the criticism raised a year before in the *Critique of Hegel's Philosophy of Right*.[84] In this latter work, Marx opposed to Hegel's claim of generality for his logical concept ('the matter of logic'), the necessity to develop 'the logic of the matter'.[85] By contrast, in the *Manuscripts* Marx no longer distinguishes between a *general ideal* necessity and a *particular ideal* necessity. He realises that the relevant distinction is that between the ideal necessity *tout court* – logic – and the determinate movement of the real. In this way, he criticises philosophical representation in all of its forms. In other words, the clear distinction between the latter and dialectical cognition was not present in the 1843 critique. So much so that, as we have seen, in 1843 Marx still saw his work as philosophical, and revolution as the realisation of philosophy. In 1844, he came to see philosophy as the epitome of representational thought, as abstract thinking or alienated thought that thinks itself. Hence, emancipation cannot be the realisation of philosophy, but rather its annihilation.

[83] It is precisely on this point that Marx's critique of Hegel parted company with Feuerbach's earlier critique. For in too hastily identifying self-mediation or the movement of contradiction as inherently tied to Hegel's absolute idealism, Feuerbach missed the methodological rational kernel contained, certainly in a 'mystical form', in the dialectic. Thus, Feuerbach did nothing to make scientific use of Hegel's insight into the general form taken by the movement of 'real determinateness', i.e. self-negativity or self-mediation. Schmidt (1971,

On the other hand, in 1844 Marx started to get to grips with (or at least made explicit) something which he seemed to have overlooked in the 1843 critique regarding the 'rational kernel' to be recovered from the Hegelian dialectic. As argued above, Hegel was aware of what was at stake in the development of the 'scientifically correct method', namely, the overcoming of the externality between the ideal necessity of thought and the inner life of the object of scientific cognition characteristic of the 'understanding'. Notwithstanding the inverted nature of his proposed solution, the fact remained that he was the first thinker not only to pose the problematic and attempt a solution explicitly, but

---

p. 28) correctly notes this, although he does not develop the discussion along its methodological implications. By contrast, Colletti (1973) fully endorses Feuerbach's identification of self-mediation with absolute idealism and attributes that view to Marx as well. As Caligaris and I (2014) have argued elsewhere, Colletti's argument is not only unconvincing but actually relies on a misreading of the dialectic of the 'finite' in Hegel's *Science of Logic*.

also to discover the *form of scientific cognition* with the power to overcome that externality, namely, the dialectic. Many years later, Marx gave recognition to this revolutionary aspect of Hegel's thought in the oft-quoted passage from his Postface to the second German edition of *Capital*:

> The mystification which dialectic suffers in Hegel's hands, by no means prevents him from being the first to present its general form of working in a comprehensive and conscious manner. With him it is standing on its head. It must be turned right side up again, if you would discover the rational kernel within the mystical shell.[86]

However, my claim is that this rediscovery of the rational kernel in the distinction between the *representation* of reality and the *ideal reproduction in thought of the movement of the real* began to take shape already in 1844, precisely through the critique of the inverted solution put forward by Hegel. Against the latter's *absolutisation* of logic by giving it the form of the dialectic, Marx searched for the *overcoming* of logic by giving the revolutionary science of the proletariat precisely that general form discovered by Hegel.

The fact that this was the key issue in, and main result of, Marx's critique of Hegel's *Logic* becomes evident when one considers the direction that Marx's subsequent work took in *The Holy Family*, *The German Ideology* and *The Poverty of Philosophy*. In those texts, Marx directed his criticism at the vulgar version of Hegel's thought as represented by both the Young Hegelians and Proudhon. As we shall see in the following chapter, through the discussion of Marx's critique of Proudhon, the main point of his attack, ceaselessly made throughout those pages, was that instead of reproducing in thought the real movement of history and bourgeois society, Proudhon (as much as the Young Hegelians) replaced the latter with an ideal, logical necessity. I now turn to this question.

CHAPTER 3

Marx on Proudhon: The Critique of Dialectical Logic and the Political Determination of Science as Practical Criticism

Introduction

As much as his critique of the Young Hegelians, the central aim of Marx's critique of Proudhon was eminently political. In actual fact, one could say that the latter was even 'more' political than the former. This is not just because of the nature of the critique, but also because of its historic-political significance. While, in the last instance, the critique of the 'True Socialism' of the Young Hegelians remained within the boundaries of a discussion among a small circle of radical 'intellectuals', the critique of Proudhon involved a political intervention right at the heart of the dominant ideological form of the continental workers' movement as a whole. As Shortall notes, Proudhonian socialist ideas had a strong grip among the artisans and craftworkers who composed the great bulk of the working class at that time in continental Europe.[1] On the other hand, by that time Marx and Engels had already made their first contacts with the existing forms of socialist activism and politics in London and Paris, and were attempting to get involved in the organisational aspects of the immediate political action of the working class of their time.[2] Hence the political urgency of Marx's text.

However, from the perspective of Marx's scientific development, the significance of that polemic against Proudhon went beyond his immediate political concerns. As we shall see, three main interrelated questions emerge from Marx's critical engagement with Proudhon's works. First, Marx made explicit that the materialist inversion of the Hegelian dialectic entailed more than the overcoming of its speculative nature, through its application to the 'material questions' of political economy. This approach can only lead to the conversion of the dialectic into another form of *logic* and, therefore, remains within the uncritical alienated realm of representational thought. Thus we encounter again the crucial *methodological* significance of Marx's text. Secondly, in *The*
